3rd. The trees, after being well and carefully planted out, should have a small mound of earth about six inches to a foot high, drawn up round their stems, with the double object in view of preventing the trees being heaved by the frost through access by water around the collar of the tree where the newly-placed earth will wash down, and of keeping away mice from barking the tree, as when a mound of earth is round it, every wind that blows will drift away the snow, leaving the spot too much exposed for mice to harbour in. If the orchardist intend planting largely, it will be well for him to go himself to the nursery and see to their being properly removed from the rows where they are growing at the right time. In no case accept trees that have been taken out of the rows and heeled in on the ground, as there is no telling how early they may have been dug out. No trees should be dug until the season is far advanced or the frost has been sufficiently severe to stop the circulation of sap so as to allow the young wood to ripen and become solid. Be particular to get only such varieties as you think will succeed and prove profitable in your section, and have them so labelled that you may know each sort when dividing them out for planting. No honest nurseryman will try to substitute one kind for another that is desired, unless the orchardist consents to it.—J. M.

The Seed Crop of 1870.

Messrs. William Bryce & Co., seed merchants, London and Glasgow, state in their Price Current of this autumn that the quality of the seeds generally appears satisfactory, and they are inclined to thing, judging from their own observation, that the showers of August have greatly alleviated the evil effects of the drought of the spring and early summer.

Peas and beans are considerably below the average, early varieties having suffered most. Turnips are very deficient, and it is generally expected that prices must rule high throughout the season. Cabbages are good, but short in quantity. Mangolds and carrots are a light crop. Other seeds show a fair average.

The Gladiolus in Poor Soil.

Being a great admirer of that beautiful flower, the Gladiolus, I beg to state, in support of the opinion of some growers, that this flower does exceedingly well with me in very poor soil, very little better than brick rubbish, and the atmosphere is not very good, the place being only one mile from London Bridge. I mention these facts for the encouragement of those who may think soil and situation may not suit this flower.

I have had spikes equal to those I saw this season at the Crystal Palace; they have been admired by experienced gardeners.—William Edwards, Bermondsey.

Hamilton Horticultural Society.

The Fall Exhibition of this Society was held in Hamilton, on the 15th September. The tables were well filled with a fine display, especially of fruit and vegetables, and there was every evidence that the members take an interest and just pride in their Society. We had not time to take a special note of the many entries, nor of those articles to which prizes were awarded, having been hurried away before the judges had completed their work. One collection of new seedling potatoes we noticed, which were exhibited by Mr. John Freed, raised from seed saved last autumn from the Early Rose, fertilized with the Buckeye, which were of very fine appearance, and many of them very large.

Brantford Horticultural Society.

This Society held its autumn exhibition on the 13th September. It was the best which the Society has had. The number of entries was 780, and the display was very fine. The citizens of Brantford manifested their appreciation by a large attendance.

The success which has attended these Societies is gratifying to every friend of horticulture, and there is no reason why every town in Ontario may not have a successful Horticultural Society, except it be the supineness of the horticulturists themselves.

What is Fruit?

Fruit, in all its astonishing variety of texture, colour, and shape, is a modified leaf.

In the peach, the stone is the upper skin of a leaf, hardened so as to protect the kernel or seed; the pulp is the cellular tissue of a leaf, expanded and endowed with nutritive properties for the sustenance of the embryo plant; and the beautiful downy skin on the outside is the lower cuticle of the leaf, with the sun-bloom upon it, the hollow line on one side of the fruit marking the union between the two edges of the leaf.

In the Orange, the juicy lips enclosing the seeds are the different sections of the leaf developed in an extraordinary manner, while through the transparent skin of a ripe gooseberry the ramifications of the leaf-veins are distiuctly seen.—*The Gardener.*

Lawn Grass Seed.

Mr. William Saunders, in the *Horticulturist* for July, says that he finds the following mixture to produce the most perfect permanent lawn, viz:—

One bushel Red Top, *Agrostis vulgaris.*
Two bushels June Grass, *Poa pratense.*
One quart Timothy, *Phleum pratense.*
Two pounds White Clover, *Trifolium repens.*

These quantities are to be mixed and sown on one acre of land, the soil having been first thoroughly prepared.

Evergreens in the Orchard.

F. R. Elliott writes to the *Horticulturist* that many years ago he recommended the plan of planting here and there, irregularly but discriminately, *among* the apple, pear, or other fruit trees, more or less of Norway Spruce, White Pine, Scotch Pine, and other evergreens. Since that time he has repeatedly mentioned the subject, and called attention to the superiority of this plan over the one usually recommended, that of planting *a belt* of evergreens. His arguments are clear, and the wonder is that this plan has not been more generally advocated. He urges that the trees will not occupy any more space than when planted in a belt, and would exert their ameliorating influence throughout the whole of the orchard, instead of protecting only a breadth of say 100 feet. He says he has repeatedly witnessed the beneficial effect of contiguous evergreens in the bloom and fruiting of pears, apples and peaches, and calls attention again to this plan, from having again seen their protective influence in a plot of dwarf pear trees.

The Best Show Pelargoniums.

Attraction, Foster—Soft rosy lilac, novel and good.

Bonnie Charlie, Hoyle—Rosy crimson, with black top petals.

Charles Turner, Hoyle—Orange scarlet, rich dark upper petals, a grand flower of extra fine quality.

Claribel, Hoyle—A charming light variety, pure white, with a bright carmine spot on the top petals.

Corsair, Foster—Bright purple, with top petals, a novel and fine flower.

Conflagration, Foster—Rich crimson, with black blotch on top petals.

Diadem, Hoyle—Rosy purple, with deep shading, rich dark top petals.

Emily, Hoyle—Delicate rose, large and fine.

Empress, Foster—Rose, with maroon spot on top petals.

Envoy, Hoyle—Warm rose, with shaded dark top petals.

Example, Hoyle—A grand flower, rich deep crimson rose, black top petals.

Heir-loom, Hoyle—Rich orange rose, with large black blotch on top petals.

Hermit, Black—White, with large reddish maroon spot on top petals.

Lady of the Lake, Foster—Orange rose, very dark maroon top petals, a fine but rather late blooming variety.

Lilacina, Black—A pleasing pale lilac, coloured flower, not of the best form, but charming for its line of colour.

Maid of Honour, Foster—Light rosy pink, with small dark blotch on top petals.

Marion, Foster—A noble flower, rose, with dark maroon top petals.

Mary Hoyle, Hoyle—A beautiful flower, warm orange rose, small dark blotch on top petals, lit up with bright orange.

Queen of Roses, Beck—Lively purple, shaded with rose, new in colour, very attractive and fine.

Regina Formosa, Beck—Rose, dark top petals.

Royal Albert, Hoyle—Warm rose lower petals, large dark blotch on top petals, a large and very fine flower.

Sœur de Charite, Foster—Lower petals, rich painted orange, black top petals, a fine and striking flower.

Sunbeam, Hoyle—Rose lower petals, dark top petals, remarkably fine blooming.

Troubadour, Foster—Lively orange pink, dark spot on upper petals, a fine and striking flower.

William Hoyle, Hoyle—A very dark variety, lower petals warm rose, tinted with orange and red, very fine and novel in character.

Covering Grass Seeds.

A correspondent of the *Farmer* (Scottish) gives the results of some experiments by himself and a neighbour, showing that, in ordinary field culture, the prevailing opinion among farmers that the nearer the surface clover and grass seeds can be sown and covered, the better chance they have of succeeding, is contrary to actual experience.

His neighbour sowed a ridge of his clover seed along with the grain in the plough furrow, and found the clover to be much better on this ridge than on any part of the rest of the field sown in the ordinary way after the grain had been sown, and covered with light seed harrows. He sowed several plots of 100 seeds each in his garden, covering them at various depths, and found the proportion to grow to be as follows with rye grass:—

Plot 1.	Sown on surface,		6 ont of 100	grew.	
" 2.	Covered 1 inch....		50	"	"
" 3.	"	2 "	69	"	"
" 4.	"	3 "	47	"	"
" 5.	"	4 "	1	"	"
" 6.	"	5 "	0	"	"

With Red Clover it resulted in

Plot 1.	Sown on surface.		35 out of 100	grew.	
" 2.	Covered ½ inch.		40	"	"
" 3.	"	1 "	25	"	"
" 4.	"	1½ "	38	"	"
" 5.	"	2 "	5	"	"
" 6.	"	3 "	2	"	"
" 7.	"	4 "	0	"	"

The conclusion he comes to is that mixed grass seeds should be well harrowed in, while clover does not require so heavy a covering, a half to one inch being sufficient.

Flemish Beauty.—A remarkably fine specimen of the Flemish Beauty pear was sent to our office by Mr. W. B. Phipps, one of the most successful amateur horticulturists in this city, and who would stimulate his fellow-labourers in the same field if his name appeared often amongst the exhibitors at our horticultural shows. The pear weighed 17½ ounces, and measured in its longer circumference 13¼ inches, and 12 inches in the other.

Entomology.

The Onward March of the Colorado Potato Beetle.

A WORD TO CANADIANS.

Last July, while spending a few days in Ontario, we ascertained that this most destructive insect had just invaded the Dominion at two different points, namely, near Point Edward, at the extreme south of Lake Huron, and opposite Detroit, near Windsor, at the southwestern corner of Lake St. Clair. These are precisely the two points at which we should naturally expect to first meet with it on the Canadian border; for all such beetles as fly into either of the lakes from the Michigan side would naturally be drifted to these points. As we know from experience, many insects that are either quite rare, or entirely unknown on the western side of Lake Michigan, are frequently washed up along the lake shore at Chicago; and these are so often alive and in good condition, and so often in great numbers, that the lake shore is considered excellent collecting ground by entomologists. In like manner grasshoppers are often washed up on the shores of Salt Lake, in Utah, in such countless numbers that the stench from their decomposing bodies pollutes the atmosphere for miles around. We have not the least doubt, therefore, in view of these facts, that the Colorado Potato Beetle could survive a sufficient length of time to be drifted alive to Point Edward, if driven into Lake Huron anywhere within twenty or thirty miles of that place, or if beaten down anywhere within the same distance while attempting to cross the lake.

How truly is Mr. Walsh's prophecy being fulfilled, that the northern columns of this great army would spread far more rapidly than the lagging southern columns.

Now, what will our Canadian brethren do? Will they stand by and listlessly see this pernicious insect spread over their territory like a devouring flame, as it has done over the Western and Central States; or will they make some determined and united effort to prevent such a catastrophe? Of one thing our friends across the border may rest assured—they have not here a sham and braggart Fenian army to deal with, but an army which knows no retreat, and whose members, though of small and insignificant stature, will fully make up in number what they lack in size.

When we calculate the immense loss, amounting to millions of dollars, which this insect has cost the Western States during the past nine or ten years—when we contrast the healthful and thrifty aspect of the potato fields in Ontario and in those States to which this potato plague has not yet spread, with the sickly, denuded, or Paris-green-besmeared fields at home—but above all when we reflect that, nothing preventing, it will infest the whole of Ontario within, perhaps, the next two, and at farthest within the next three, years—we feel that it is high time to make some effort to prevent its onward march through Ontario, if ever such an effort is to be made. The warnings and instructions given by the agricultural press, and through our own columns, will avail but little, as they reach the few only. It may be, and doubtless is, true that successful culture, as our country becomes more thickly settled, will be confined to the intelligent and well-informed; yet the fact nevertheless remains, that the masses will do nothing to ward off an evil until they are forced to it from necessity. The plodding, non-reading farmer will take no notice of the few bugs he first sees in his potato field, because they do him no material injury; but when the bugs have increased so as to make it a question of "potatoes or no potatoes" with him, then his energies will be aroused. But alas! his best efforts, at this time, often prove unavailing, and he has to spend days to accomplish that which a few minutes would have accomplished before. We therefore fully expect to see this great army of bugs continue its eastward march without hindrance, unless other preventive measures are taken than those already employed. A standing premium offered by the Minister of Agriculture, Mr. Carling, for a given number of beetles, or for the greatest number collected and killed in one season, or for the cleanest and best field of potatoes, of a given number of acres, within the infested districts along the eastern shores of the lakes mentioned and those of the St. Clair river, might, and undoubtedly would, be the best means of stamping it out and of keeping it out of the Dominion.

No doubt that, in suggesting any expenditure of money for such purposes, our Canadian brethren will deem us over-enthusiastic about "small things," and over-anxious for their welfare. Well, be that as it may, we don't forget that there is considerable of Uncle Sam's territory beyond Niagara. It is a mere matter of dollars and cents, and we venture to say that, when once this insect shall have spread over Ontario, a million dollars would be freely spent to accomplish that which will then be almost impossible, and which a very few thousands would effectually accomplish now—namely, its extermination from the Dominion.

An excellent chance is now afforded in Ontario—almost surrounded as it is by lakes—to keep this destructive enemy at bay. In the summer of 1869, reports of this insect's ravages, and of its progress eastward, came thick from Wisconsin and Indiana; but no organized effort was made to check it, and indeed there was very little chance of doing so. It is now fast spreading through Ohio; and, according to Dr. Trimble of New Jersey, has already reached Pennsylvania. Uncle Sam can not well prevent its onward spread around the southern shore of Lake Erie, through Pennsylvania and eastward; but, if it can be effectually resisted between Point Edward and the Detroit river, there will be little difficulty in preventing its crossing at Niagara. A victory would indeed be gained if, by intelligent effort, this grievous pest could be kept out of Upper Canada, while it is devastating the potato fields on all sides in the States; and Minister Carling would add to his well-deserved popularity by making the effort, whether it succeeds or not.

PARIS GREEN AS A REMEDY.

While on this subject it may be well to say a few words about the use of Paris green. This substance has now become THE remedy for the Colorado Potato Beetle, and it is the best yet discovered. Having thoroughly tested it ourselves, and having seen it extensively used, we can freely say that, when applied judiciously, it is efficient and harmless. If used pure and too abundantly, it will kill the vines as effectually as would the bugs, for it is nothing but arsenite of copper (often called "Scheele's green" by druggists), and contains a varied proportion of arsenious acid, according to its quality—often as much as 59 per cent., according to Brande and Taylor. But when used with six to twelve parts, either of flour, ashes, plaster or slacked lime, it causes no serious injury to the foliage, and just as effectually kills the bugs. The varied success attending its use, as reported through our many agricultural papers, must be attributed to the difference in the quality of the drug.

We hear many fears expressed that this poison may be washed into the soil, absorbed by the rootlets of the plants, and thus poison the tubers; but persons who entertain such fears forget that they themselves often apply to the ground, as nourishment for the vines, either animal, vegetable or mineral substances that are nauseous, or even poisonous to us. Animal and vegetable substances, of whatsoever nature, must be essentially changed in character and rendered harmless before they can be converted into healthy tubers, and a mineral poison could only do harm by being taken with the potatoes to the table. That any substance, sprinkled either on the vines or on the ground, would ever accompany to the table a vegetable which develops under ground, and which is always well cooked before use, is rendered highly improbable. There can be no danger in the use of sound tubers. But the wise and well-informed cultivator will seldom need to have recourse to Paris green, as he will find it more profitable to use the different preventive measures that have from time to time been recommended.

The poison may do harm, however, by being carelessly used, and it is most safely applied when attached to the end of a stick several feet long, and should not be used where children are likely to play.

THE TRUE REMEDY

consists in preventing them from becoming

numerous so late in the season. Watch for the beetles in early spring, when the vines are just peeping out of the ground. Ensnare as many of them as you can before they get a chance to pair, by making a few small heaps of potatoes in the field planted; to these the beetles will be attracted for food, and you can easily kill them in the morning. Keep an eagle eye for the eggs which are first deposited. Cultivate well by frequently stirring the soil. Surround your fields on the outside by rows of such tender-leaved varieties as the Mercer, Shaker Russett and Early Goodrich; but, above all, isolate your potato field as much as possible, either by using land surrounded with timber, or by planting in the centre of a corn field. Carry out these suggestions thoroughly, and you will not have much use for Paris green, and still less for the scorching remedy.—*American Entomologist and Botanist.*

The Poisonous (?) Tomato Worm.

In reply to Mr. R. Wilson, of Port Huron, who has sent us a specimen, we beg to state that we have never denied the fact of there being a Tomato Worm. On the contrary, we have frequently described it and remarked upon it. But we have denied, and still continue to deny that the creature is poisonous, either from its imaginary sting, or its projected spittle. An idea has somehow or other got into the heads of the people of this country that the poor innocent Tomato Worm is as deadly as a rattlesnake, and it seems as if no amount of contradiction or proof would ever persuade them that such is not the case. We had almost intended giving up the attempt to enlighten the mind of our readers on this subject, but our correspondent's note, and a recent paragraph in the newspapers, induce us to recur to the matter once more. The latest story is that an inhabitant of Dundas was sitting under a butternut tree, quietly cogitating upon things in general. Presently, he observed something like a bur upon his coat, and on attempting to remove it, was startled to find that it was not only alive, but also stung his finger severely. At once there flashed across his mind all the terrible stories that he had heard and read about the deadly Tomato Worm, and he began to think that his hour was come—that he was about to add one more to the long list of victims slain by this venomous beast! He rushed to the house—he sent a swift messenger for the doctor—and meanwhile he "kept his spirits up by pouring spirits down!" Ere long the poison began to work upon him—he collapsed—his senses left him—his affrighted friends beheld, they thought, a dying man. But, heaven be praised! by and by he began to recover—his senses came back to him—in due time he was restored to health. Surely, you will say, this was a clear case. But no; think a moment. The man sat under a *butternut tree;* that is not the place where tomatoes are usually grown, and not a single syllable is told us about any tomato plants being anywhere near. Secondly, the worm on his coat *looked like a bur.* A Tomato Worm, as is plain from the specimen sent us, is perfectly smooth, with the exception of a tail at one end, and no more like a bur than a horse is like a porcupine. Thirdly, there *is* a spiny yellowish-coloured caterpillar—the larva of the Io Emperor Moth—that looks very like a bur when coiled up, and whose sharp spines, as we have several times mentioned lately, possess the property of stinging like a nettle when incautiously handled. This worm feeds upon a variety of forest trees, but never, to the best of our knowledge, upon the tomato. We have no doubt that it was the spines of this insect that stung the man of Dundas, and that it affected him rather more severely than usual, just as we have known a man inclined to erysipelas forced to put his arm in a sling by a mosquito bite. We have often handled this insect, and thrust its spines into our fingers on purpose to try its powers, but have never experienced more than a transitory pain and trifling inflammation exactly like that produced by a nettle. Fourthly, it is a well established fact that people often become seriously ill, and sometimes die, from mere fright. Might not this have had something to do with the wonderful case at Dundas? And lastly, it appears to have been quite forgotten that the practice of "pouring spirits down," even for the seemingly innocent purpose of "keeping spirits up," has occasionally the effect of producing insensibility, when strict moderation is not adhered to. Now, we put it to the reader, is it not better as a rule to arrive at conclusions by some more gradual and safe method than by the process of jumping?

The Hop Louse.

The first appearance of anything connected with the lice in the spring, that I have discovered, is a small green aphis on the under side of the leaf from about the first to the tenth of May. It has much the appearance of a small green grasshopper, being at first not more than one-sixteenth of an inch in length, and, if disturbed, moves around quite lively, but seldom leaving the under side of the leaf. They grow to be about three-sixteenths of an inch in length, and mature, the first of them, about the first of June, when their feet become fastened to the leaf, and, shedding their skin, they become a fly. When the fly first comes out it is a very light red, with the tips of its wings having a milky appearance. The wings soon become clear, and the colour grows to a darker red as they mature. They are as active in five minutes after they are out of the skin as they ever get, for they seldom leave the hill on which they are grown, unless in heavy winds. At the time of their first appearance the vine is from four to six feet up the pole, the aphis continuing to increase and undergo the change as above till the last of July or first of August.

After the fly has arrived at the age of from two to three weeks, they begin to deposit lice on the under side of the large leaves, low down on the pole, where they are shaded, and ascend the pole as foliage affords shelter from the sun. The aphis cannot stand the heat of the sun without shade, as they die at once when shook from the leaf to the ground in the middle of the day.

The lice, being all females, commence laying live lice, if the weather is warm, when about eight days old, and when about fifteen days old have made a deposit of from fifteen to thirty each, when, by old age, or having fulfilled their mission, they die. Their colour when young is light green, and darker as they advance. The young grow up and go through the same process and transformation for about six generations in one season, the last being the one that damages the crop, as the former remain on the leaves, and while there I have not discovered that they do any particular damage except the amount of sap they take for support. But when the fruit is so far advanced as to be ripening off, it draws on the root for all the strength, the leaves begin to mature, and the lice are forced to leave them and go to the fruit to prevent starvation. Then the first damage shows itself, the hop assuming a watery appearance, then turning dark-coloured on the inside and looking as though struck with mildew (as some have seen fit to call it rather than say they have lice on their hops). I have seen acres spoiled by turning dark in six hours, through the effect of a heavy fog on a damp day. So far there has not been a male louse in the yard, but during the last of the picking season and the last generation, some flies are seen with wings about twice as long as their bodies. These are the males, and at this time impregnation takes place for the coming year. The last seen of them is on the ground, and they soon disappear, the impregnation passing through at least three transformations.

The young lice come from the mother backward, and walk off to a safe retreat at once. I have been unable to follow them through the winter. I have tried fumigating them with charcoal and sulphur, but the lice will stand more of it than the hops. The only remedy I know of is a cold storm from the first to the tenth of August, which will clean them out, every time, so that they cannot get in sufficient force to do any damage till the very last day's picking.—E. F. L., in *Rural New Yorker.*

Let me strongly advise the incorrigibly careless to have nothing to do with bees, either on my plan of management, or any other, for they will find both time and money almost certainly thrown away.—*Langstroth.*

Correspondence.

Capacity of Root-Cellar, &c.

"Teacher," writing from Fenelon Falls, wishes to be informed what space should be reckoned in building a cellar for roots, grain, &c. The capacity of the bushel is 2150 inches; hence the ordinary rule for estimating the number of bushels of grain in a bin is to multiply together the three dimensions of the bin in inches; and divide by 2150. The rule can, of course, be easily applied for the reverse proposition of calculating the space required for grain, as well as in reckoning the amount of grain in any given bin.

The rule for measuring corn in the ear is as follows: Measure the length, width, and height of the crib in feet; multiply these three dimensions together, and the product by 4; cut off the last right-hand figure; those to the left express the number of bushels of unshelled corn. If measured in inches, multiply the three dimensions together, and divide the product by 4,300 (twice 2,150, corn in the ear occupying twice the space of shelled corn or grain); the quotient will be the number of bushels.

In calculating for roots, it will be sufficiently accurate for all practical purposes to allow one cubic foot and two-thirds (1⅔) for each bushel, or 16⅔ feet (in decimals about 16.66) for every ten bushels.

An easy mode of reckoning will be to use the rule for measuring corn in the ear; to the quotient thus obtained add one-half the amount, and you will have about the quantity of bushels of turnips in the same space. For example, suppose:—

A space of 10 feet x 20 feet x 8 feet = 1,600 feet. Multiply by 4 = 6,400 feet. Cut off the right-hand figure, leaving 640, the number of bushels of shelled corn. Add half this. 640 and 320 make 960, which would be about the number of bushels of turnips to allow for those dimensions. The relative bulk of corn in ear, roots and grain, may be calculated, in reference to the first, as half as much again as the second, and twice as much as the last. Thus, a space that would hold twenty bushels of unshelled corn would contain thirty bushels of roots, and forty bushels of grain.

Surfeited Pigs.

To the Editor.

Sir,—In answer to your Colchester, Nova Scotia, correspondent's question, (see Canada Farmer, July 15, page 260,) I would say that almost any animal having grown "amazingly fast" for ten weeks is in danger of sickness. It argues over feeding; a fault a pig is naturally inclined to, and in this case was tempted to indulge the propensity.

I have wondered if the hog cholera, of which they complain out west in the United States, is occasioned by being fed exclusively on corn. I am of opinion, (but what is the value of an opinion?) that pigs require a mixed diet; that they are by nature omnivorous, that they require a portion of animal food, and, moreover, a mixture of good clean dirt with it. Horses are clean feeders, but they, and especially sucking colts, eat dirt with avidity when they can only get it at long intervals. Pigs get dirt and grubs too, when, as in a state of nature, they live by grubbing.

Heavy losses have frequently resulted to the owners of breeding sows in consequence of keeping them penned up and confined to a diet of meal and milk, or slops.

Young pigs fed liberally with peas are subject to lameness; whether from being too stimulating, (hence inflammation), or deficient in phosphate of lime, (hence rickets), I cannot say.

Inference. Healthy stock is most likely to result from the use of a reasonable variety, and a liberal, but not immoderate, quantity of food.

BRAMLEY.

Hemp.—A correspondent who makes enquiries about hemp is referred to the number of the Canada Farmer for March, 1869, where he will find a full account of the cultivation and preparation of this crop.

The Canada Farmer.

TORONTO, CANADA, OCT. 15, 1870.

The Provincial Exhibition.

The exhibition is over, and the most ungenerous of critics would hardly pronounce it to have been anything short of a most gratifying success. It has afforded to many thousands a most enjoyable holiday, and even the skies withheld the downpour that at one time seriously threatened to mar the pleasures of the occasion. But what is most of all a subject of congratulation is the undeniable proof that has been afforded of the steady and rapid advancement of the country in what most concerns its substantial progress and prosperity. It may not be uninstructive to review briefly some of the principal features of the exhibition, which best illustrate the spirit of enterprise and the growing intelligence at work amongst us.

Taking first of all the exhibition of live stock, the rapid advancement in the art of breeding and rearing is at once apparent. Every year affords a means of comparison; but if the show which has been held during the past week is compared with the one held at Toronto four years ago, the rate of improvement will be far more easily estimated. The country has been immensely indebted to those persons who have boldly speculated in the importation of stock from Europe, and from whose efforts the whole country is now deriving a marked benefit. Prices ranging from six to seven thousand dollars for a single animal, and, in addition, all the risk and cost of transportation, have been paid, and the result is that both in thorough-bred stock and in "grades," the results have been such as to astonish not only our own countrymen, but Americans who have resorted to the exhibition. In imported and home-bred animals proof has been afforded that the first risk and outlay have been wisely and profitably incurred. When we hear of such prices as $775 being paid for a nine months' old heifer we see what an impetus has been given by the introduction of first-class stock. There is no doubt that Canada is admirably adapted to this branch of industry, and that a large and profitable business is springing up in stock raised in this country from imported cattle.

Good mutton is not to be despised, and there is yet room for improvement in the breeding of sheep for the consuming markets. The display, however, of those on which we rely for our home supply of wool was very encouraging.

Not less so was the exhibition of pigs, although limited, probably through the want of due care in the arrangements made for their accommodation. It was difficult to realize, as one passed the pens of Berkshires, Suffolks and other well-known English breeds, that the ground one trod was that of a transatlantic Colony, separated by 3,000 miles of water from the mother country. Before these comely importations, the long-legged, long-snouted aboriginal porker is fast disappearing. There is an opening for a vastly increased export trade in pork, and too much encouragement cannot be given to the careful raising of the most profitable description of hogs, a matter, by the way, not hitherto sufficiently appreciated by many of our farmers.

In the improvement of the breed of horses, as well as in the importation and raising of cattle, it was evident that a spirit of enterprise had been at work, and with equally satisfactory results.

Nor in developing the productions of the soil is Canada destined to stand second to any other country. Apples that have no rivals, luscious pears that will stand comparison with any produced in Europe, and grapes approaching very nearly to perfection, afforded specimens of what in autumnal fruits this country is

already capable of doing. In grain, in field roots, in the many varieties of the gourd tribe, in garden vegetables, and notably in potatoes, the prolific nature and adaptability of the soil was splendidly illustrated.

The many ingenious machines for lessening and assisting farm labour found crowds of admirers, and gave the most conclusive evidence of the growing intelligence brought into play in connection with economic agriculture.

What is wanted, however, both as regards agricultural machinery and other mechanical inventions is a longer term for their exhibition. We suggested on a former occasion that arrangements might be made for a show of this description, which should extend over three or four weeks, and thus repay the owners for the cost and trouble of moving and fitting their machinery. It would have the effect probably of inducing a much larger number to exhibit, besides affording a far better opportunity for study and examination. An exhibition of machinery and manufactures at Toronto, commencing say on the first of September and being open for a month, would aid rather than detract from the Provincial exhibition in October.

Perhaps in conjunction with machinery and manufactures a stimulus might be given to Art by combining an exhibition of pictures. It must be a very poor picture indeed that does not attract some one, and the crowd in the north wing showed how much interest its contents excited. But, taken individually, there was really nothing of a particularly striking character to be seen there. Nothing, that is, on which an artist appeared to have laboured to show how much real genius he possessed. The collection had too much the appearance of a number of friendly contributions rather than of competing works of art. Professional artists are doubtless much engaged in the work of instructing others, and amateurs of sufficient talent to make a striking display, are necessarily few in number. But, having regard to the immense and direct influence the painter's art has on the mind of a nation, it would be well to consider by what means any existing defects in this department may be most effectually remedied and higher efforts successfully encouraged.

Passing over the very creditable exhibition of miscellaneous articles, there are two other sections which possess a certain domestic interest: the Poultry and the Apiarian departments. Of the first, although some good specimens were exhibited, it must be acknowledged that, on the whole, it was a failure. Several of the leading breeders were not represented at all, and both in quality and variety the show was this year certainly wanting. So much innocent pleasure and amusement are to be derived from poultry-keeping that it cannot be too generally encouraged.

Bee culture in Canada may be said to be in its infancy. But no one, who listened, either to the discussions of the apiarians in convention, or to the conversation going on around the exhibited hives, could fail to be struck with the great earnestness of the "bee-masters," or the actual love they feel for their avocation. As a source of commercial profit as well as amusement, bee-culture should be promoted as extensively as possible.

In thus reviewing briefly the impressions the Exhibition has created on our mind, it is, of course, necessary to remember that all this marvellous display of industry, intelligence, and energy, is shown in a country that has none of the advantages which great territorial proprietors or vast accumulations of wealth are able to afford to the arts and agriculture of Europe. What we see is the honest result of hard-handed toil, of thought quickened by necessity, or of single-handed enterprise. If we consider under what difficulties, and in how short a time so much has been achieved, we shall be able to form a just idea of the natural gifts of the country, and the sturdy resolution of its people.

The Colorado Potato Beetle.

In another column the reader will find an article on this most destructive insect from the *American Entomologist*—a well-known scientific journal edited by Mr. C. V. Riley, the accomplished State Entomologist of Missouri. The writer, in warning us of the terrible devastation to which we are exposed, proposes a mode of prevention which, we think, ought to be adopted by our Minister of Agriculture, namely, that a price should be set upon the head of the pest, so that a premium should be offered for every hundred, thousand, or ten thousand, captured in Canada, and duly sent in to some competent examiner. As the Fruit Growers' Association have proved in the case of the Plum Curculio, people will willingly adopt measures for the collection and destruction of a noxious insect when they are given so much per hundred for all they put to death, while they will not go to the same trouble for the sake of reaping a far higher reward, the salvation of their crop of fruit, or whatever it may be. We have no doubt that if Mr. Carling would offer to pay a dollar a hundred, or—if that is too much—a couple of dollars a thousand, for all genuine Canadian specimens of the Colorado Potato Beetle, the spread of the pest would be very greatly checked, if not altogether stopped.

Another mode of prevention that we also desire to urge very strongly upon the Government and the inhabitants of the western part of this Province, is the marking off of a tract of country about ten miles in width, all along the border line between the foot of Lake Huron and the head of Lake Erie, with the exception, possibly, of a portion of the eastern shore of Lake St. Clair, and stopping the culture of the potato throughout that whole tract during the prevalence of the pest in the neighbouring State of Michigan. This may seem a hard measure, and too much to demand of the people of that region; but is it not better that they should buy their potatoes for a season or two, than that they should lose their whole crops for years to come, and allow this pestilent creature to desolate the whole Dominion from Sandwich to Gaspe? To mitigate the privation, it might be advisable to allow any one within that region to grow not more than a quarter of an acre for household use, on the condition that it should be isolated from any other potato patch, and that the owner should guarantee to carefully destroy every Colorado beetle that alights upon it. The very least that should be done in the emergency is this restriction of the growth of the crop to small isolated patches, such as can be attended to with a reasonable hope of keeping the insect in check. Large areas it will be next to impossible to protect.

To carry out these regulations in thorough strictness—for nothing else will do—trustworthy persons should be appointed, with proper instructions, in every municipality throughout that portion of the country. But "what a frightful expense," says the ratepayer. Yes, it will be an expense, and it is a serious matter. Were the cholera, however, raging on our bordors, should we not go to some expense to ward off the infection from ourselves? If the cattle plague threatened us from Michigan, would not some stringent regulation be adopted to prevent its crossing the border? Were one quarter of a town in flames, would we not willingly blow up or tear down a belt of houses to prevent the spread of the devouring element? And why not take similar measures of prevention to keep off from our country a foe whose ravages will surely prove as serious a pecuniary loss as any cattle plague or raging fire? If you do not believe it, visit the States of Iowa, Wisconsin, Missouri, Illinois and others, or ask their inhabitants, and you will soon learn the terrible powers of this beetle, and shudder at the thought of its approach.

"Prevention is better than cure." It is far easier, far cheaper to keep the insects out, than to check them when once established in the country.

Notes on the Weather.

During the greater part of September, the rainy character of the season has prevailed, which was very embarrassing to harvest operations. The amount of damage done varies much in different localities. From some quarters accounts reach us of good crops gathered in fair condition, whilst others report small yields or great loss in harvesting. But taking the Province as a whole, the returns will show about an average production of grain, while root crops and fodder will probably be abundant. The meadows and pastures have presented, in consequence of the warm and showery weather, a most unusual greenness of aspect, more resembling the verdure of English fields than the ordinary bare or burnt condition of the land towards the close of our Canadian summers.

The following notes are compiled from the records of the Toronto observatory:—

The mean temperature of the month was 62.4, being 4.4 higher than the average, and 1.7 warmer than September, 1869. Its average temperature was higher than that of any similar month in thirty years, with only two exceptions, namely, 1846 and 1865, which were respectively 63.4 and 64.5.

The highest temperature occurred on the 1st—78., and the lowest on the 20th—45.8.

The quantity of rain was greatly in excess of the usual rain-fall, being 6.794 (average of of 30 years being 3.694). Of this amount 2.285 inches fell on the 15th and 1.200 inches on the 30th. The number of rainy days were eleven, differing only slightly from the usual number. The amount of cloudiness was about the average, and the numbeo of clear days 8; partially clear 15; clouded 7.

Thunder-storms more or less severe occurred on the 3rd, 9th, 15th and 25th, and lightning alone on the 1st, 2nd, and 8th.

The prevailing winds have been from the north and east.

Influence of Cities on the Atmosphere.

Alkali and other chemical works on an extensive scale are more or less found in or near all manufacturing towns in England, and in order to prevent or rather mitigate their deleterious influence on the public health, an Act of Parliament was passed a few years since, subjecting all such works to official inspection. In Dr. Angus Smith's last report, much interesting information is contained as to the effect of large cities, and especially of factories, in contaminating the atmosphere. The following extracts express some of his principal conclusions:—

The rain from the sea (Western Islands) contains chiefly common salt, which crystallizes clearly.

The sulphates increase inland before large towns are reached.

The sulphates rise very high in large towns, because of the amount of sulphur in the coal used, as well as decomposition.

When the air has so much acid that two or three grains are found in a gallon of rain-water, or forty parts in a million, there is no hope for vegetation in a climate such as we have in the northern parts of the country.

Free acids are not found with certainty where combustion or manufactures are not the cause.

Experiments in the direction indicated above may enable us to study and express in distinct language the character of a climate, and certainly of the influence of cities on the atmosphere.

In Manchester, in 1867, the maximum acidity of the rain was 7.39 grains per gallon, and the minimum 0.31.

The total acid in rain collected from various sources bears the following relationship:—

Row, Dumbartonshire.....	100.00	= 1
Whiston, ten miles from Liverpool.....	470.67	= 4⅔
Birkenhead.....	523.20	= 5¼
Liverpool.....	938.21	= 92-5
Waterloo, on the shore	961.98	= 9½
Newcastle on Tyne 1054.73		= 10½
Manchester	1175.54	= 11⅔
Near an alkali work.....1539.27		= 152-5

We can scarcely be surprised, after glancing at this table, at the rapid decay of stone in certain localities, compared with others, and the long endurance of buildings of antiquity which are far from large towns, and in a pure and open air, such as the Parthenon and Pyramids of Egypt.

Alkali works liberate free acid, which is brought down in rain solution, to the great injury of vegetable life. Large brickfields have often been found particularly deleterious in this respect, and to destroy even trees in the direction of the prevalent winds.

Prize List.—We defer, as usual, the publication of the award of prizes at the Provincial Exhibition till the list has been officially revised. In our next monthly issue we hope to give it complete and accurate.

The Pleasant Valley Fruit and Wine Reporter is the title of a new semi-monthly paper, published at Hammondsport, N.Y., under the editorial care of A. L. Underhill, Esq., assisted by an able corps of associate editors, at the subscription price of one dollar per annum. The first number is a very handsomely illustrated eight-paged sheet, full of valuable information concerning grapes and wines, to which subjects it will be specially devoted. This new branch of industry is making great progress in America. We learn from this initial number of the *Fruit and Wine Reporter* that the capital invested in the manufacture of wines in that locality is eight hundred thousand dollars, and the vineyards are estimated to be worth two and a half millions of dollars, and give employment in the various departments to some two thousand persons. The average annual yield per acre, taking the whole acreage in bearing, is three thousand pounds. The vines that have been planted are more than half of them of the Catawba variety, about one-seventh Isabella, and about one-fourteenth Delaware, and the same of Iona. Very few Clintons have been planted, and it is thought by those competent to judge in these matters, that the Clinton has not been sufficiently prized. It is expected that the crop this year will not fall short of six thousand tons, selling to the wine cellars at ten cents per pound. We wish the Pleasant Valley *Fruit and Wine Reporter* every possible success, and shall be happy to place it on our exchange list.

Poultry Yard.

Poultry Keeping on a Large Scale.

The difficulty and frequent failures in keeping a large number of poultry in one spot has often been discussed in these columns. In England the attempt has failed; in France, a very few successful examples have been reported. The only hope of overcoming the difficulties of the enterprise appears to be in giving the poultry a widely extended range. On this subject the experience of Mr. Warren Leland, of the Metropolitan Hotel, New York, as given in a recent meeting of the New York Farmers' Club, and published in several of our American exchanges, is interesting and instructive. He says:—

"I have found that for every hundred fowls you must give up at least an acre. But rough land is as good as any. Hens naturally love the bush, and I lop young trees, but leave a shred by which they live a year or more. These form hiding places and retreats for them. In such places they prefer to lay. I have great success, and it depends on three or four rules, by observing which I believe one can make a good living by hens and turkeys.

"1. I give my fowls great range. Eighteen acres belong to them exclusively. Then the broods have the range of another big lot, and the turkeys go half a mile or more from the house. The eighteen acres of poultry yard is rough land, of little use for tillage. It has a pond in it and many rocks, and bushes and weeds, and sandy places, and ash heaps, and lime and bones and grass, and a place which I plough up to give them worms.

"2. When a hen has set I take her box, throw out the straw and earth, let it be out in the sun and rain a few days, and give it a good coat of whitewash on both sides. In winter, when it is very cold, I have an old stove in the house, and keep the warmth above freezing. There is also an open fireplace, where I build a fire on cool wet days. They dry themselves, and when the fire goes out there is a bed of ashes for them to wallow in. Summer and winter my hens have all the lime, ashes, and sand they want.

"3. Another reason why I have such luck is because my poultry yards receive all the scraps from the hotel. Egg-making is no easy work, and hens will not do much of it without high feed. They need just what a man who works requires—wheat bread and meat. As to breeds, I prefer the Brahmas, light and dark. I change the cock birds every spring, and a man on the farm has no other duty than to take care of my poultry. I have often 3,000 spring chickens."

Classification of Fowls.

W. B. Tegetmeier, the well known English writer on poultry, writes to the London *Field* as follows:—

The question, What is the best breed of fowls? is often asked. It is, however, as difficult to reply to as would be the query, What is the best kind of horse or dog? Before it could be answered, the requirements of the inquirer must be stated, and all the particulars respecting his conveniences for poultry-keeping taken into account.

In the *American Agriculturist* for June, 1870, an attempt has been made to give an extended classification of fowls, arranged according to their merits, regarded from different points of view. This is not exactly in accordance with English experience, and therefore in place of copying it verbatim, I present an arrangement of my own, freely acknowledging my indebtedness for the idea to the above-named journal :—

A. Prolificacy. — Non-sitters — Hamburghs, Leghorns, Spanish, Houdans, Crevecœurs, and Polish. Sitters—Brahmas, Cochins, Dorkings. (For winter layers, Brahmas and Cochin pullets are superior to all others.)

B. Value for Table.—First-rate table fowls for market—Dorkings, La Fleche, Houdan, and Crevecœurs. For home-use—Cross-bred Dorkings and Brahmas, cross-bred Crevecœur and Brahma, Brahmas, Cochins.

C. Hardihood.—Hardy—Brahmas, Cochins, Houdans, Leghorns. Hardy, if with unlimited range — Spangled Hamburghs, Game, Crevecœurs. Delicate—La Fleche, Dorking, Polish, Sultans.

D. Size of Eggs.—Layers of large-sized eggs—Crevecœur, Spanish, Houdans, La Fleche. Layers of medium-sized eggs—Leghorns, Cochins, Brahmas, Dorkings, Polish, Game. Layers of small eggs—Hamburghs, Bantams.

E. Size of Birds.—Large—Brahmas, Cochins, Dorkings, La Fleche, Malays, Crevecœur. Medium—Spanish, Leghorns, Polish, Game. Small—Hamburghs, Sultans, Silkies. Diminutive—Bantams.

F. Activity. — Active fowls — Hamburghs, Game, Game Bantams. Less vivacious—Spanish, Leghorns, Dorking, &c. Very domestic and quiet—Brahmas, Cochins.

G. Incubation. — Good sitters — Brahmas, Cochins, Dorkings, Game, Farm-yard fowls, Bantams, Silk Fowls. Non-sitters—Hamburghs, Spanish, Leghorns, Polish, French Breeds.

This arrangement is probably correct in the main, though perhaps in some respects the experiance of other breeders may not exactly accord with my own.

Rearing Young Turkeys.

Young turkeys are almost proverbially delicate, and many persons have so great a fear of the trouble and uncertainty of rearing them, that they will not make the attempt. I believe that turkeys, with proper management, can be raised as easily as chickens, and with as great a degree of certainty.

I have known poultry women who have reared them for years in succession without losing a single chick, whilst in other hands fifty per cent. or more have gone to the bad.

My own method of procedure is to follow nature as far as possible. I make my turkey nests on the ground; or if in a paved house, in large shallow boxes half filled with mould that can be damped at intervals. The hens, unless they come off regularly, are lifted off to feed, and then supplied with grain with a liberal hand.

When the young ones are hatched they are left undisturbed under the hen until the next day. No attempt is made to cram them; an absurd practice, which interferes most injuriously with the due digestion of the yolk that is absorbed into the intestines at birth, and constitutes all the food required for twenty or thirty hours after hatching.

The first food given them is egg beaten up with an equal bulk of milk, and baked into a soft custard; this is alternated with crumbled bread mixed with milk, to which oatmeal is added in a gradually increasing proportion. Ants' eggs are given if I can get them, but if not the custard is continued for a fortnight or three weeks. Quite as important as any other part of the dietary of young turkeys is the supply of green food, and many persons chop up nettles, onions, etc., with the meal; but if young turkeys are watched when grazing, it will be observed that they prefer eating bitter herbs belonging to the natural family *compositæ*, or compound flowered plants, such as the dandelion, etc. The common lettuce belongs to the same tribe, and I have this year fed largely on it. The greediness with which young turkeys devour this plant is remarkable. At three weeks old a dozen turkey chicks will eat four or five large lettuces in a day, and they even seem to prefer them when running to seed, at which time there is abundance of bitter milky juice in the plants. At the age of a month they will begin to peck a few grains of wheat or barley; but bread and milk, and meal, should form the staple of their food for the first two or three months of their lives.

Most persons say that young turkeys are particularly delicate when they are "shooting the red." This is not to be wondered at when it is remembered that they are generally put on whole grain, without milk, long before they arrive at that age, and suffer accordingly.

Another point of the highest importance in feeding turkeys, or young birds of any kind, is the hour at which they get their first repast. If the birds have their first meal deferred until long after daylight, they have been hungry for two or three hours, and suffer very much.

To be successful in rearing these, or any other young birds, they must either be supplied over night with their first meal, or the poultry maid must be up with the lark. There is no better plan than putting the hen and chicks, for the first month or two, in a closely wired aviary at night, which is open to the early sun, and lettuce and a good supply of soft food can be put under a coop, so that the hen cannot eat it, and there will be found but little left an hour after daybreak. —W. D. Tegetmeier in *London Field*.

Apiary.

Artificial Impregnation.

We are glad to know that some of our Canadian bee-keepers are turning their attention to artificial impregnation of queens. We have succeeded once in three cases tried this season.

J. Maitland, Kilmarnock, writes as follows :—

"I succeeded in introducing the Italian queen received from you all right; her brood is nice and bright; am well pleased with her. The Italian bee, when pure bred, appears milder in disposition than the black bee. I cannot say so with the hybrids.

"I am trying to breed queens and have them impregnated in confinement, on Mrs. Tupper's plan. I have not proved it out as fully as I expect to this season, but I have plans working which I think will test the matter beyond dispute.

"About two weeks ago I took two young queens out of my impregnating boxes and put them into hives about five miles away, where there are none but black bees kept. If they produce pure Italians it will be another proof of the system. A few days since I had the bees and queen leave one of my nucleus hives—no doubt for want of brood in the hive. I succeeded in catching the queen, placed her in the impreguating box, where I kept her for about 48 hours, and returned her to a nucleus hive; in 2½ days she was laying eggs.

"I had also a queen bee hatched without any wings. I tried the experiment with her, but when I was returning her to the nucleus hive, a bee stung her and she died. I was pretty sure she had been impregnated, as I found two dead drones. I am continuing the process; perhaps I may get another wingless queen ere long."

It is not necessary to remove the small hives away if they have plenty of honey. The queens can be returned to the hive, and all the bees kept confined until she lays.

Productive Honey Season.

Mr. Wells, of Thurlow, writes :—"With reference to last year's yield of honey, I can fully endorse the remarks of Mr. J. H. Thomas in your journal. Comparing my returns this year with those examples of productiveness cited in his article, I find that mine are even more favourable.

"Fifty-eight stocks in the spring, and one half of them nearly starved, owing to the poverty of the previous year, have given me an aggregate of one hundred and two stocks, all in good condition. The yield from these for the season has been over 2,700 lbs. One stock alone netted over 150 lbs., from the top of the hive, and in addition a large swarm, from which in turn I got two boxes of 14 lbs. each. The Italian bee I find an excellent worker."

Beware of Humbugs.

I have been informed that some unprincipled fellow is travelling through the township of Clarke, imposing upon bee-keepers, and taking their money for instructing them how to remove the honey from the hive, and still have the bees do well, by giving them a compound or preparation made up by himself. It appears that he avoids or passes by the more intelligent bee-keepers, and plays his "little game" with such as are not well informed in bee culture.

I have repeatedly called attention to these unprincipled fellows in this journal, and warned bee-keepers against having anything to do with them, and I again repeat the warning, for every stock so treated is ruined, and every five dollars paid for such a process is worse than lost.

J. H. THOMAS.

Whence Came Our Honey Bees?

That our common honey bees are of foreign origin is universally admitted; but it is still a matter of dispute whence they came, or when they were introduced; though it is generally supposed that they were brought from England. Those in the Eastern States may have been thence derived; but we doubt whether those in the Middle States came from the same quarter.

In a pamphlet republished in the "Historical Magazine," Vol. VI., September, 1862, page 268, entitled "Good Order Established" in Penneylvania and New Jersey, in America, by Thomas Budd, originally printed in the year 1685, occurs the following passage, referring to those then colonies:

"Bees are found, by the experience of several person that keep them, to thrive very well."

Hence it is obvious that bees must have been kept in Pennsylvania and New Jersey long enough prior to the close of 1685, to make the term "experience" applicable to those who kept them. It is also well known that bees were abundant, even in the forests of Pennsylvania, while they were yet comparatively rare in New England, where they were introduced from the "mother country" in 1680. They must thus have been derived from a distinct importation, if not from a different stock. We incline to the latter conjecture, and for this reason: We know that the bees in the Middle States were free from the ravages of the bee moth till about the year 1805, and that this pest came thither from New England. How long the insect existed there, before it became so devastating as to attract the notice of bee-keepers, is not known; but its progress south and west is traceable, and establishes the fact that it was a stranger south of the Hudson. Though not noticed early, it was doubtless imported with the first bees carried to New England, for it is a fact that importations of Italian bees, whether made from Italy direct, or from Germany, always bring with them the moth or the miller, or both. This we believe is invariably the case. We are credibly informed that the trunk and wardrobe of Herman, who accompanied the stocks imported by Mr. Parsons, of Flushing, were thus infected; and observation shows that it is so common an occurrence that it may be regarded as invariably true. It follows, we conceive, that the bees of Pennsylvania and the Middle States came from a country where the bee moth did not exist. That country, and the only country in Europe thus free and having early communication with the New World, is Sweden; and the Swedes and Finns had settlements in Pennsylvania and Delaware as early as 1627. Mead was their favourite beverage; and they would certainly be likely to carry with them, in their emigration, the means of supplying themselves with it, and would thus introduce a bee *not troubled with the moth*. *They* could do this, and emigrants from no other country could; for the bee moth was not known in Sweden till within the last twenty years—the desire to possess the Italian bee having carried that baneful pest thither also.—Editor *American Bee Journal*.

Poetry.

Sword and Plough.

FROM THE GERMAN OF WOLFGANG MULLER.

There once was a Count, so I've heard it said,
Who felt that his end drew near;
And he called his sons before his bed,
To part them his goods and gear.

He called for his plough, he called for his sword—
That gallant good and brave—
They brought him both at their father's word,
And thus he his blessing gave:—

"My first born son, my pride and might,
Do thou my sword retain,
My castle on the lordly height,
And all my broad domain.

"On thee, my well-loved younger boy,
My plough I here bestow;
A peaceful life shalt thou enjoy,
In the quiet vale below."

Contented sank the sire to rest,
Now all was given away.
The sons held true his last behest
E'en till their dying day.

"Now tell us what came of the steel of flame,
Of the castle and its knight;
And tell us what came of the vale so tame,
And the humble peasant wight."

Oh ask not of me what the end may be;
Ask of the country round;
The castle is dust, the sword is rust,
The height but desert ground.

But the vale spreads wide, in the golden pride,
Of the autumn sunlight now;
It teems and it ripens far and wide,
And the honour abides with the plough.

Household.

Preserving Eggs

A sensible writer in the *Western Rural* gives several methods of preserving eggs, as follows:—We have tried several modes and never found any difficulty in keeping eggs any desired length of time for culinary purposes, seemingly as good and fresh as when first laid. Our principal mode has been that recommended by Mons. Chas. Jacque, which, from several years' experience, proved one of the best we ever tried; having succeeded in keeping eggs nice for use from six to eight months after they were laid. He says:—The most certain and most lasting mode of preservation consists in covering the eggs in a jar filled with lime water, recently prepared, and keeping them in a cool place. The lime water is prepared from quick lime r that which has been slacked but lately, by placing it in a quantity of water greater than would cover the eggs. The milk of lime which is thus formed is allowed to stand several hours. The clear liquid which separates itself from the excess of lime used is the lime water, which is poured off for use. Lime water not only prevents the evaporation, since the eggs are plunged in the liquid, but the alkali which it holds in solution closes the pores of the shell, and prevents all fermentation, either of the eggs or of the organic matter which the water might contain."

We have had good results also from packing eggs in very dry barrel salt, which have kept for months in a well preserved state. Our mode was to stand a box or stone jar in a cool place in the cellar, put therein a layer of salt, then one of eggs, with the large ends downward, taking care that the eggs did not touch one another; continue this practice until the jar or box is full; cover the box, and let it stand without disturbing until the eggs are needed for use. We have packed eggs in this way in June and July, and found them in January and February perfectly fresh in looks, and having no stale or musty taste when brought to the table.

How to Make Old Salt Pork as Sweet and Tender as Fresh Pig's Meat.—There is no humbug about this, though it may look like it. We have tried it, and we know the person who discovered it, Mrs. Washington Champion, who thus has fresh, tender meat the year round. It is simple, but requires some labour. The principle has been approached before. The thing is done by boiling and frying alternately, and finishing off with sweet milk, boiling and frying also. Here is the receipt: Boil slowly in several waters till sufficiently freshened. Then boil in another water till reduced to a fry. The frying should not take long—about fifteen minutes. Fry for a while till about half done or less, so as to get the water well out, else it will be snappish thereafter. Turn off the fat and pour on sweet milk, which boil down another fifteen minutes, and finish by frying brown. Now you have something that is perfectly tender; the oil is not all fried out, as is the case with some meat. The lean is tender with the rest. Pork even tainted or otherwise objectionable, may thus be treated to great advantage. Will each house-wife that reads this receipt try it, and get the benefit of it? It is no humbug.—*Country Gentleman*.

Agricultural Intelligence.

Provincial Exhibition.

The twenty-fifth annual exhibition of the Provincial Agricultural and Arts Association of Ontario was held in Toronto during the first week in October. The weather previously had been wet, and on the opening day of the Fair (Monday) rain came down with scarcely any intermission, making the ground nearly everywhere muddy and swampy. But the succeeding days, though not bright, were fair, and the show was a complete success. The following record is compiled from the reports made each day, and consequently describes the events as transpiring rather than past. The account here given is also confined to those departments which are of more immediate interest to the agricultural reader.

HORSES.

BLOOD HORSES.

As in former years there are only a very limited number of entries in this class. The show of blood horses at our Provincial Exhibition presents a rather unfavourable comparison with other classes, more especially as regards numbers. We consider the show of blood horses as a class only middling, although there are a few very good specimens of the blood horse exhibited. The class for aged stallions presents the largest numbers of entries, and several valuable and well-known animals are shown, as "Jack the Barber," by "Vandal," a favourite Canadian sire; "Extra" by "Endorser," out of "Natura." "Extra" is very well bred, and was a first-class racehorse, and three years ago he left Kentucky for the sum of seven thousand five hundred dollars. Such a fine horse must prove a desirable acquisition to this country. In the list of entries is the old horse "Kennet," who has competed successfully in former years, but in the present exhibition we expect he will have to succumb to younger competitors.

In young stock the entries are very few indeed, and the principal exhibitors are the Messrs. White, of Bronte, Mr. Shedden, of Toronto, and Dr. Morton, of Bradford. The Messrs. White always compete largely in this class. Among the young animals our choice is the colt by "Lightning" out of "Vinnie Ream;" he is a beautiful bay, of fine size and action, and shows many of the fine points of his illustrious sire, and, judging from present appearances, he cannot fail to be a racehorse. Mr. Shedden also shows "Julia Adams," with a handsome colt at her foot by "Thunder."

Although several of our enterprising agriculturists and breeders are certainly deserving of every encouragement for their importation of blood stock, there is yet great room for improvement. We have quite enough of thoroughbred stallions throughout the country; our deficiency consists in the limited number of well-bred mares. Many of the mares at present used for breeding purposes have been put to the stud after a severe racing campaign of a number of years, thereby becoming enervated and in a great measure unfitted for successful brood mares. We believe it would be well worth the attention of our breeders, and also well repay the outlay, to import pure bred and young mares of good size, and put them to the stud before being weakened by severe training and racing. No doubt the raising of half-bred horses proves profitable in many cases; but the thoroughbred will always command the highest price, if he has size and style. Our severe climate may somewhat militate against the proper development of the thoroughbred, as compared with milder climates, such as Kentucky, Virginia, &c.

The show of heavy draught horses has never been excelled at any previous Exhibition held in this Province, and the turn out of to-day, both as regards excellence and numbers, amply testifies to the fact that Western Canada possesses the finest heavy draught horses to be met with on the continent of America. Of late years breeders have been stimulated by the large prices realized for horses for the New York and other markets. A great many of the horses shown have been imported from England and Scotland, and Canadian enterprise has always secured the best specimens. In the class for stallions, four years old and upwards, there are twelve entries, and nine of these are imported. Mr. Kemp, of Weston, again exhibits the beautiful bay horse, "England's Glory," one of the finest horses of his breed. He is the winner of several first prizes at the Provincial Shows, and although only five years old, he weighs upwards of twenty-one hundred pounds. Mr. Robert Ferris, of Richmond Hill, shows his four year old horse that gained the first prize at London last season. "Sir Walter Scott," the property of Mr. Porter, of Darlington, is again on the grounds. Mr. Buckland, of Guelph, shows a very fine young horse, bred by Mr. Wilson, of Bayham Hall, Suffolk, England. We believe the show of aged stallions cannot be surpassed at any exhibition in Britain.

There are eight competitors in the three-year old class. Mr. Jas. Lawrie, Scarboro, shows his two imported horses, "Tinto" and "Farmer's Fancy." They are both fine specimens of the Clydesdale, and were bred by that well-known breeder, Mr. Muir, of Hardington Mains, Lanarkshire, Scotland. Mr. Kitchen, of Whitby, shows a very fine Canadian bred horse, equal to many of the imported ones.

There are twelve two-year old stallions shown. Mr. Duncan McConnachie exhibits his grey colt, that gained the first prize as a yearling. He is a very fine young horse of perfect symmetry. One of the finest young horses at the exhibition is the two-year old colt, the property of Mr. Ferris, and imported two weeks ago from Scotland. This colt is one of the best ever imported into this country; he gained the second prize at the Highland Agricultural show, in July last, and he is likely to be placed in the first position here. Mr. Simon Beattie exhibits a very stylish colt, bred by Joseph Hope, of Cumberland, England. Mr. John Beith, of Clarke, Mr. McFarlane, of Pickering, and Mr. Morrison, show very good horses.

Of yearling colts there are five entries. Fourteen fillies are exhibited, five three-year olds, six two-year olds, and three yearlings. Mr. Jeffrey, Whitby, shows a filly by Conqueror that is likely to be placed first in her class. Mr. Davidson, of Pickering, has his filly that gained the second prize at London, and Mr. Neal Taylor is again present with the filly that gained the first prize as a yearling last season. In this class the well-known breeder of horses, Mr. Beith, of Darlington, is also an exhibitor.

There are twelve brood mares exhibited. Mr. McConnachie shows two, both bred by exhibitor, one of them is a superior animal and will be hard to beat. Mr. Beith, Mr Davidson, and Mr. Crawford, also exhibit excellent mares.

In section ten, Mr. Hendrie, of Toronto, shows a pair of handsome grays, and Mr. Simon Beattie a pair of imported Suffolk mares, five year olds—their combined weight being upwards of thirty-four hundred pounds. D. McLean, York, and Morrison, Scarboro', also show very fine teams.

On Wednesday the Judges commenced their task of judging the blood stock. The entries being few there was very little difficulty in deciding the prizes. Dr. Morton gained the first prize for aged stallions, with the chestnut horse "Extra," who also received the diploma for the best horse of any age. Mr. Shedden's colt, by "Lightning," was much admired, and received the first prize in his class.

The road and carriage horses were the next on the list, and in the section for aged stallions there were twenty-six entries. The horses exhibited were mostly superior animals, and the Judges experienced considerable difficulty in deciding. Mr. Orr, of Georgetown, was again successful with his horse by "Whalebone," who was also placed first on the list at the London and Hamilton Exhibitions. He is a very fine horse, possessing size, strength and action. Mr. Buckland, of Guelph, exhibited an imported coaching horse, of good style and symmetry, and bred by Mr. Harrison, of Yorkshire, England. This horse, although it was a splendid animal, failed to secure a prize. In the class for three year olds, the well-known importer of valuable stock, Mr. Simon Beattie, showed the imported horse "Grand Turk," a very promising horse, of superior style and action.

The two year olds and yearlings were quite a show of themselves. Mr. Simon Shunk, Vaughan, gained the first prize with his yearling colt, by "King Tom." Messrs. Lake & Fraser, of Fredericksburg, showed a pair broke to harness. The Association's Diploma for best stallion of any age, was awarded to Mr. Orr's horse.

In the class for French Canadian stallions there were six animals exhibited. Mr. R. Wells, of King, secured the first prize with an exceedingly handsome horse, of perfect build and action. Mr. Sylvester, of Scarboro', was awarded a prize for his horse "Montreal Telegraph." The road and carriage fillies were numerous, and some most excellent animals were exhibited.

Immediately after the prizes had been awarded in this section, the prize animals were paraded around the Judges' stand, and minutely inspected by His Excellency the Governor-General, and also by the Lieutenant-Governor, both of whom seemed much pleased with the handsome show of horses.

The matched pairs of carriage horses, although very good, were not equal to the show of some former years; this year they were arranged under two sections, the one for horses sixteen hands and upwards, and the other for horses under sixteen hands. When placed under the standard, only three of the competing teams were found to stand the measure

Mr. Grand, of Toronto, and Mr. Carpenter, of Whitby, showed two very good pairs of heavy carriage horses.

For horses under sixteen hands, a pair of handsome and good stepping greys were awarded the first prize. Of single carriage horses there were upwards of forty entries, and as in the preceding section the show was not quite equal to that of last year's Provincial.

There were sixteen saddle horses entered, and the first prize was awarded to a handsome chestnut mare, the property of A. Smith, V. S., Toronto. In this class Mr. Hendrie, and Mr. Leys of Toronto, exhibited very fine animals. After the saddle horses were shown, the ponies came forward, and considerable amusement was afforded the spectators by a good contest of speed between two diminutive specimens of the equine species.

AGRICULTURAL HORSES.

The Province of Ontario cannot be surpassed for horses of the above description, and the exhibition of the agricultural horses proves highly attractive to the farming community. The first on the list is the aged stallions, twenty-one entries. In this section the judges had a difficult and arduous task to perform, as a number of the competitors were very evenly matched. The red ticket was given to a brown horse by "Coachman," the property of Mr. Coultor, of Brampton. The winner of the first prize stands over sixteen hands high, with strong back and fine head, and action like a carriage horse. Mr. Crawford, of Scarboro, showed a very useful looking animal. Two or three of the animals shown appeared better fitted for the heavy draught than this class.

The judging of the horses was finished at noon Thursday. The show of heavy draught stallions was particularly fine. England's Glory was awarded the first prize, this being the third year he has gained a first prize at the Provincial. In the three-year old class Mr. Mason, of Tuckersmith, Huron county, gained the first prize with his brown horse bred by Mr. Green, Lincolnshire, England. Mr. Mason's horse is a perfect model of symmetry.

In the two-year old class the chief attraction and winner of the first prize was Mr. Robert Ferris's recently imported colt A. 1, bred by Mr. Kerr, of Castle Douglas, Scotland. As we formerly mentioned it was the general opinion that this colt was the best specimen of the heavy draught on the ground.

The colt stands nearly sixteen hands high, is a beautiful brown, with a white stripe on the forehead, long rangy nock, short back and powerful loins, and is an excellent mover for a horse of his class. Such a valuable animal is likely to prove of great benefit to the stock raisers of this country, and we are sure Mr. Ferris will meet with that encouragement which his enterprise deserves. When the three winners—Mr. Mason's horse, England's Glory, and Mr. Ferris's colt—came together to compete for the diploma for the best stallion of any age, the Judges, after a careful and minute inspection awarded the red ticket to the latter. This decision was received with applause by the spectators around the ring. In the afternoon all the prize takers were exhibited together, and it was the universal opinion that the present exhibition of horses has never been equalled in this country. The careful decision of the Judges has given general satisfaction.

CATTLE.

By 9:30 a.m. Wednesday the Judges in the cattle classes got to work, and did not get through till late in the afternoon. In the Shorthorn and Hereford classes, they gave great encomiums on the stock brought in, and the newly imported stock of Mr. John Miller, of Pickering, elicited high praise from them. In some of the Shorthorn classes great difficulty was found in coming to a decision upon the merits of the animals presented for their inspection, and the services of J. R. Page, of Sennett Co., N.Y., and J. Mackelcan, of the *Canada Farmer*, were more than once called in to assist in the decisions. George Miller's herd was detained on the way from Northern Ohio State Fair, and did not get up in time.

SHORTHORNS.

In aged bulls seven came into the ring, and after much discussion the prizes were awarded, 1st to "Oxford Mazurka," 2nd to "London Duke," and 3rd to "Ontario John." A fairer one could not be given. In three year old bulls ten came into the ring, a tolerably even lot, and not much to choose from, nor any of particular merit. 1st prize goes to "Oxford Chief," 2nd to "Sir Colin Campbell," and 3rd to "Darling Duke"—all red and white bulls. Eight came in of two year old bulls; among them we have the finest lot on the ground, and "Fawsley Chief" deservedly gets 1st, while "Bell, Duke of Markham," is placed 2nd, and "Grand Duke of Cambridge" 3rd—a decision that might well be reversed to be satisfactory to good judges. In the yearling bull class only five come in; 1st goes to "Kosciusko," as we expected; while "President Grant" gets 2nd, and "Orion" 3rd. In the bull calf class there are no less than sixteen enter the ring. "6th Grand Duke of Moreton" easily obtains 1st; but there is much diversity about the other prizes, which are finally awarded, 2nd to "Sir Henry," and 3rd to "Joe Johnstone." The whole class is good, and another year will doubtless see some much improved, while others may go down. The 1st prize one is a most promising animal for the future. Thomson's newly imported "Grand Duke of Orange" though entered, was not shown. For the diploma six enter, and it at once goes to "Fawsley Chief," that may be considered as the very best Shorthorn bull now in Ontario. The aged cow class is a most magnificent one, and can hardly be exceeded anywhere. Nine enter, and after much time spent, and a close and critical examination, the prizes go, 1st to "Cherry Bloom," 2nd to "Rose of Strathallan," and 3rd to "Gola," all imported from Great Britain. The three year old class only brings out five, but they are all first-class. 1st to "Clara Barton," 2nd to "Miss Margaret 4th," 3rd to "Dominion Belle." These decisions are somewhat open to criticism, and a reverse position of the 2nd and 1st prizes would probably be more correct; and "Queen of May" is certainly better than the 3rd prize cow. In 2 years heifer class, six enter, and the 1st prize goes at once to "Minnie Annandalle," just imported; "Rosamond" being placed 2nd, and "Cambridge 10th" 3rd—a position that might well be reversed with credit to the judges. In the one year old class there are six in the ring, and a fine lot they are. The competition for 1st is close between "Christabel" and "Sylvia," both imported this Fall, but the former is lame from getting hurt in her stall, and so "Sylvia" gets 1st, while "Christabel" is placed 2nd, and "Empress" is placed 3rd. In the heifer calf class, nine come in; 1st goes to "Princess," 2nd to "Rosa Bonheur," and 3rd to "Lady Bell." For the herd prize, there are but two herds; that of F. W. Stone, comprising bull "Grand Duke of Cambridge," cows and heifer "Isabella 12th," "Miss Margaret, 4th," "Cambridge, 10th," "Morning Glory," and "Duchess of York, 8th;" and that of John Miller, comprising bull "Fawsley Chief," and cows "Cherry Bloom," "Rose of Strathallan," "Gola," "Lorena," and "Nelly Bly." Miller easily gets the prize, and the judges say a better herd has never yet been shown, every animal in it being first-rate.

HEREFORDS.

As will be seen by the prize list, Mr. Stone had the field to himself, though he is beaten for 1st prize for aged bulls, which goes to "Robin Hood," a bull of his own breeding, though now out of his hands.

AYRSHIRES.

The competition in this class is very close and keen. Mr. Laurie's aged bull "Avondale Farmer," 1st prize, is not easily beaten. J. L. Gibb, of Compton, Quebec, had entered several of his fine herd, but none of them put in an appearance. Mr. Thomas Thompson, of Williamsburgh, has no less than 8 head imported this fall, arriving from sea only two weeks ago, and he gets many prizes with them. His 1st prize aged cow, "Diamond," is a fine one, as is J. P. Wheeler's 1st prize three year old cow. Mr. Thompson's imported 1st and 2nd prize two year old heifers, "Rossie, 3rd," and "Rossie, 2nd," are good ones.

GRADES.

The class for grade cattle embraced only 41 entries, but though not nearly as numerous as one would expect to see, nevertheless, as regards quality, contained many animals little inferior to thoroughbreds, if not themselves thoroughbred. All that were shown were evidently crosses of short-horn blood on native stock, up to an extreme point, and the prizes went mostly to men who are large breeders of short-horns. There is something wrong about this. The grade class is the only one which the generality of farmers in Canada can fairly expect to have to themselves, and get some encouragement for using thoroughbred males to their cows, and it is hardly fair to them that the great stock-breeders, in addition to carrying off the prizes in the classes of which they make a specialty, should bring animals that are practically purebred to contend against the more humble efforts towards improvement of their less fortunate brethren, who have neither the capital nor advantages they have. It might be worth while for the Association to consider whether it would not be advisable to restrict the entries in the grade classes to animals of native stock, having less than four crosses of pure blood in them, and also to give prizes for females of each grade cross, say Short-horns, Herefords, Devons, and Ayrshire, so as to bring out the respective merits of each cross on our native stock, and show what each can attain to in its own sphere of improvement. This would be fairer to the small farmers, and give at least a modicum of encouragement in their efforts at improving the general stock of the country.

SHEEP.

The regret which the miserable condition of the sheep pens could not but cause was aggravated when at length on Wednesday morning the animals were brought from various quarters, where they had as it were been hidden, to make their appearance before the judges; for a finer lot of sheep in all the classes has never, perhaps, been seen at a Provincial show. The chief breeders of this stock in Ontario were present to maintain their reputation by specimens that had not before been surpassed; and several new and very valuable importations added an unwonted interest to the exhibition. It was extremely unfortunate that the public should not have enjoyed a good opportunity of seeing the display. Almost the only dry spot to be found in the space allotted to sheep was a planked causeway between the two centre sheds. On this flooring the judges took their station, and the animals were brought before them in succession for examination; while the throng of spectators, eager to have a sight of the various lots, crowded around the judges, and very much hindered and embarrassed them in the discharge of their duties. Every exhibition shows more and more the importance of having judging done early, and before the general public are admitted to the grounds. Until arrangements are made to secure this, the judges can hardly escape the annoyance of a promiscuous crowd about them, and visitors will in most cases fail to gratify their legitimate

curiosity as to the awards. When these are decided and ticketed, a much greater interest is felt by the spectators.

In regard to the total number of entries, there is a falling off from last year, but this is entirely due to a decrease in the class of Leicesters, and is nearly counterbalanced by a marked increase in the number of Cotswolds. The other classes, in the two years, numerically correspond very closely. The Cotswold sheep are a remarkably fine lot. In aged rams the first prize was awarded to Mr. John Snell, of Edmonton, for a very grand specimen of the breed, who thus takes precedence of Mr. Miller's imported animals. The 2nd prize was given to one of four remarkably well-bred sheep that came out to Mr. Miller last year, but had not previously been exhibited in this country. James Russell, of Markham, took the third prize.

The shearling rams were a very large and a very meritorious class, in which all the principal breeders competed, but Mr. Stone swept the honours with his two beautiful imported shearlings that arrived in the Province a few days ago. Their wool is of remarkably fine quality, and though not large they are first-class specimens of the breed. In the section of ram lambs, also very numerous, Mr. John Miller took the first prize, and Mr. Russell, of Markham, the rest. In aged ewes Mr. George Mitchell, of Darlington, carried away the first prize. A very close competition in shearling ewes was decided in favour of Mr. J. Miller, who took precedence of Mr. Snell. The merits of the animals were, however, very evenly balanced, and good judges might have reversed the decision. The last section in this class also caused the Judges great perplexity. After a long consultation, Messrs. Stone, Snell and Russell divided the honours in the order named.

The next class on the prize list was also remarkably good, in which Richard Lean took the first prize for aged rams over an imported animal just received from Battersby, Lincolnshire, by Mr. Snell. Both were magnificent types of the Leicester breed. In shearling rams, Mr. Snell was first, and Mr. Adam Oliver, of Downie, second. The ram lambs were a beautiful lot; T. Teasdale, J. Snell, and James Russell taking the premiums. Among the aged ewes, a recent importation by Mr. Snell, from the flocks of Messrs. Walcott and Campbell, took the first prize; but in shearling ewes, this generally successful exhibitor gave place to Mr. W. H. Wallbridge, who distanced all competitors with a fine ewe just imported from Great Britain. The wool, like that of other first-class English-bred Leicesters, was remarkably fine, but the animal was not in show trim. In England this ewe had taken a first prize at the Yorkshire Show, where she had beaten a first prize winner at the Royal Society's Show. Mr. C. Walker, of London, exhibited the best ewe lambs of this breed; but the whole class was good, if not altogether first-class. Among the meritorious lots was a pen of six rams, just imported by Thomas Douglas, of Lobo, which arrived too late for competition.

The falling off in our Leicesters as compared with former shows is partly to be attributed to the want of fresh importations of pure blood for the last two or three years, and partly to the injudicious intermixing of Cotswold and Lincoln blood into many of our Leicester flocks, with the object of increasing size, but at the exponse of symmetry and early maturity, which are the highest characteristics of the Leicestor as a breed. There is much more need of pure blood Leicesters to cross on our common stock, or even the Cotswolds, than ever there was, now that good mutton readily commands so high a price, and early lambs are at a premium.

The Southdown class was fairly represented, and, as usual, Mr. Stone secured the lion's share of the honours. The most beautiful specimens of this breed on the ground, and, perhaps, on the continent, were two ewes that could not easily be matched for neatness and symmetry of form, or closeness and fineness of wool. Among the extra entries were four Lincoln ewes, exhibited by W. H. Wallbridge, of Belleville, who had just imported them from Great Britain. One of these had gained the very highest honours at home, having won a first prize at the Royal Society's show, and also at the great Lincolnshire show, held at Sleaford, besides a similar distinction at the Yorkshire show in Wakefield. They were very large sheep, and no one would suppose they were only shearlings. A ram of the same breed, imported along with them, had died. The judges awarded two prizes to the best of the lot.

There was a larger display than usual of Merinos, with several good specimens of the breed. J. & W. Smith, of Burford; R. D. Foley, of Darlington; A. Young, of Barton; and J. W. Johnson, of Grantham, were the principal exhibitors.

There was a good lot of fat sheep. The chief interest of the show in this class was centred in the Prince of Wales' prize, which this year was offered for the best lot of Leicesters, comprising one ram (one shear and over,) one ram lamb, three aged ewes, three shearling ewes, and three ewe lambs. There were six entries for this prize, but only three exhibitors, Mr. Snell, Mr. C. Walker, and Mr. James Russell, actually competed. The three lots, as they stood in row before the judges, presented a beautiful appearance and elicited general admiration. The decision was unanimously given in favour of Mr. Snell.

SWINE.

Under favourable circumstances there is little doubt but that the show of pigs this year would have been superior in numbers, as well as quality, to that of preceding exhibitions, but the miserable weather and the wretched condition of the pens has deterred many of the best and most enterprising breeders from sending their pigs to the grounds. Consequently, though in most of the classes the number of entries exceeds that of last year, a very large proportion of the pens are empty, and the actual show is numerically small. The only class in which the entries show a falling off is in that for large breeds, and this is neither a matter of surprise nor of regret, for though undoubtedly the larger varieties have their use, especially for purposes of crossing, and should not therefore be altogether neglected, yet for general utility, of early maturity, thrift and economy in feeding and delicacy of flesh there can be no question but that the smaller breeds are the most desirable. They are more easily managed, command a readier sale in the market, and will at a very early age attain weights the most convenient for the general consumer, giving the farmer a quicker return and a larger increase in proportion to the amount of food than the mammoths of the family. That this opinion is prevalent would appear from the very few representatives of the large breeds to be met with at the present exhibition, while in all the smaller varieties, though from causes already explained the show is small, the entries are increased.

In the class of improved Berkshires there is the largest competition, and many animals of very great merit were on the ground. Most noticeable among these were two splendid imported boars, one the property of Mr. George Roach, of Hamilton, the other of Mr. John Snell, of Edmonton. The first of them is 13 months old, squarely built, with sufficient length, a good head and fine skin, and altogether an excellent type for the breeder. Mr. Snell's importation is a little younger, and perhaps of rather larger frame. Both are extremely valuable acquisitions to the country. Among the sows in the same class are three importations that arrest the admiration of every visitor. They are the property of Mr. Miller, of Pickering, and constituted a prize pen at the late Oxford Show of the Royal Society of England. They are nine months old, evidently of the same litter, though one of them, exhibited by herself in another section, seems to carry the palm for all the best qualities of this favourite variety. It certainly would not be easy to find a better model of porcine excellence. Apparently, they are as gentle and almost domestic in disposition as they are symmetrical in form.

Mr. George Roach exhibits some beautiful animals in the same section, though we understand that he withheld some of his best stock on account of the condition of the pens. Other exhibitors, whose names have on former occasions been found on the prize list, have again contributed to this very meritorious class.

Another breed which is unusually well represented is the Essex, of which there are purer specimens than we ever remember to have seen at any Provincial Exhibition. Here again Mr. Roach is pre-eminent; and his imported specimens as well as the progeny of former importations, are admirably adapted to display the points of this choice breed, and to render it a favourite on this side of the Atlantic. Amongst the aged boars Mr. Roach exhibits the sire of some of his best stock, a noble animal two years and eight months old, imported from England in 1868. He also shows a number of younger ones that bid fair to rival their parent in excellence. Among the females of this breed Mr. Roach shows a ten months old sow, that is without exception the prettiest animal of the kind that we have seen. As in all good pigs the head is remarkably small, the snout short, the legs short and fine, the body squarely and compactly built, with the back broad so as to give it the character known as "table-back," making altogether a perfect study for the breeder. A number of younger sows of the same breed, shown by this enterprising exhibitor, give promise of rare excellence. They were all in prime condition and beautifully clean. Mr. McCrae, of Guelph, is also a prominent exhibitor of this variety and shows good specimens.

The Suffolks are another good class, containing some very choice animals. Here also Mr. Roach has the lion's share of enterprise and honour. He shows largely in every section, some of the animals being importations of 1868, or the present year. Among such a number of first-class animals it is not easy to select the choicest; but a 10-months boar and a 10-months sow took our fancy as much as any of the lot. Messrs. Featherstone, of Toronto Township, and Main, of Trafalgar, are also meritorious exhibitors in this class.

Of other small breeds, or rather mixed varieties and crosses of no particular breed, there is a miscellaneous collection, with a few animals of merit among them. Altogether the show in this class of stock, notwithstanding the serious drawbacks of the wretched accommodation, gives evidence of marked improvement, which is, no doubt, chiefly due to the enterprise of those breeders who have imported good blood from Great Britain.

POULTRY.

In contrast to other miserable quarters, the Poultry shed, an entirely new structure erected for the purpose, has been very well constructed, and those who remember the pools and mud through which they had to wade on the occasion of the last Provincial exhibition in Toronto, in order to gain a sight of the bedraggled birds, in coops too much exposed to the weather, cannot fail to be struck with the greatly improved accommodations provided this year. This consists of a spacious shed, 200 feet long by 24 feet wide, the sides being composed of open slats, so as to allow abundant ventilation, while a tight roof keeps all perfectly dry. The centre is occupied by two double tiers, one above another, of nest and commodious coops. A strong railing extends all round to prevent visitors crowding too closely, and there is ample space outside this railed enclosure for a considerable crowd to walk without inconvenience. The front of each coop is a separate wooden frame with upright wires. The whole of this front is lifted out to admit or remove the birds, and is kept in place by a button. This may be found inconvenient, and it strikes us that the plan adopted by the Poultry Association is preferable—namely, removing one or two of the wires, or providing a very simple door, for which one of the upright wires serves as a hinge. We think the two tiers of coops better than three, as none of the birds are raised to a height where they cannot readily be seen. In many respects this poultry shed is a model worthy of imitation, and is decidedly the best that has yet been erected at any agricultural exhibition in Canada. Very few birds indeed were in their places on the first two days, and not more than half the coops were filled at any time.

Although the number of entries in the poultry class was considerable, the show itself was by no means a large one, and as the accommodation provided was ample for an exhibition of very large proportions, the effect of empty coops, with birds only here and there, detracted from the success of this department. The fault of such a result lies entirely with those who made entries but did not send their specimens—an injustice which we have frequently noticed and condemned. All the birds could easily have been shown on one side of the row of coops, and would have looked better thus collected together. But the manager had of course no alternative than to leave the coops for expected occupants, according to his catalogue.

We miss in the present exhibition some prominent exhibitors. Mr. Bogue is the only representative of London. He has some of the best birds in the exhibition. The first and second prize pairs of White Dorkings are his, and very beautiful birds they are. In coloured Dorkings, Mr. Van Ingen, of Woodstock, takes the first prize with a splendid pair. The Golden Polands of Mr. Bogue are also fine specimens, and Mr. McGrath, of Toronto, shows a good pair of the same variety.

Game fowl are not in their usual force; Cochins are also very far behind the splendid display to which we have recently become accustomed. Mr. McLean Howard and Mr. H. M. Thomas show two good specimens of the Partridge variety. Brahma Pootras are somewhat better represented, but not in their usual numbers. H. M. Thomas shows the best birds of this breed, both of the light and dark varieties. The latter are the progeny of the fine birds imported two years ago by Mrs. Varley, and that attracted so much notice at the second exhibition of the Ontario Poultry Association. In Golden Hamburgs, Mr. McLean Howard showed, as usual, beautiful specimens of this most graceful variety. Mr. Van Ingen had two pairs of Houdans. In Bantams, the most remarkable pen was a pair of very small and pretty game, shown by J. Main, of Trafalgar. The show of geese was fine, and the number of competitors respectable. There were also some good pens of ducks. The Aylesburys of Mr. Bogue and Mr. J. Forsyth, were particularly worthy of notice. Among the young birds the last-named exhibitor had some good specimens, which were the produce of imported eggs. Mr. Howard also showed some dark Brahma chickens of similar origin. There was only a small show of pigeons. Mr. McGrath showed a good lot of carriers, pouters and tumblers; but there were very few other entries.

On the whole, without detracting at all from the merits of many of the specimens, we must say the exhibition of poultry is a decided falling off from those of recent years; and it is evident that there is room and need for the Poultry Association to bestir itself to keep up or revive an interest in this branch of stock raising.

IMPLEMENTS.

No branch of the exhibition suffered more from the bad weather than the implements department. The continued rain of Monday made exhibitors afraid to bring their machines on the ground, and in many cases we failed to find the owner or attendant of such as were on view. Many of the implements had not even a ticket attached, and we frequently returned in the vain hope of finding some guide in our perplexity. From such causes as these, the report of this interesting department will be briefer and less finished than we could have wished. The first articles, and probably those of most importance, are the steam engines. They are represented by the rotary engine and portable boiler manufactured by Messrs. Hamilton & Son; also, that of Messrs. Waterous & Co., of Brantford, the latter in full operation, driving a portable steam sawmill, with lath mill and double edger, so arranged as to edge a board on both sides at once, and, at the same time, to be quite under control of the operator. The vast number of these saw-mills in use seem to point them out as having met with public approbation. This being the only moving piece of machinery driven by steam in actual work, is a source of general attraction, and it is much to be regretted that some arrangement by which the various other machines could be worked has not been carried out—the attractions of the more ordinary machines in actual operation being far in excess of the more elaborate whilst at rest. This firm have been before the public for many years, and all accounts coincide in awarding to them the credit of having first constructed the clipper mill now exhibited. We know that a mill of the same construction as this one was exhibited formerly in Toronto, and at once sold for exportation—we believe to Africa. To guard against the difficulty of casual breakage in a foreign country, some portions were made in duplicate, but we have been led to believe they were never required. One great peculiarity of the engine is the adaptation of the circular slide valve, and when engines on a somewhat larger scale than the one exhibited are used for driving flouring mills, a most simple and effective cut-off is attached, whereby an immense saving of steam is effected. The great advantage of the portable clipper mill consists in its being so readily adapted to any locality, and it can be erected in a few hours without any extensive building, as is usually required. Driven by the same engine now shown is their far-famed shingle machine, which is capable of turning out a large quantity of work each day. Another addition the enterprising firm have lately made to their merchant saw-mills is their pony saw-mill, by which an immense quantity of narrow boards for fencing, siding or flooring can be cut, and with the minimum amount of labour, as the machine in question is entirely automatic and self-setting. We lately visited a large merchant mill, built by Messrs. Waterous & Co., in which this new addition was working, and from the satisfaction expressed by the owner at the work performed, it would seem to be a great success.

Dickey, Neill & Co., of Toronto, exhibit a complete iron saw-mill "rig," the saw frame being of iron, instead of wood, as ordinarily used. They seem to have combined all the American improvements and some of Canadian invention. Amongst others we notice the "log mover," being constructed to be effected by friction, instead of the old ratchet wheel; also a new feed-motion, supposed to be more efficient than the old plan. A great saving of heavy lifts is effected by the "log turner," a machine so arranged that when a slab is taken off the log and it becomes advisable to roll the log over, this machine accomplishes in a moment, by the power of the engine, the work of two men, that would occupy double or treble the time. A double edging machine, is so arranged as to have one saw movable on the shaft, and capable of being moved out or in, in a moment, thus cutting and edging both edges of a rough board at once. They show one of Earl's steam pumps, direct action; and one of Cole's water wheels, of the turbine shape, which is claimed to be a great improvement on those now in use; various castings from green sand, and hand forgings.

PLOUGHS.

Ploughs were well represented, and some very handsome ones were exhibited. Those of John Gray and Co., of Glasgow, Scotland, created much speculation on their merit as two-furrowed ploughs. The iron ploughs were in considerable number, and of excellent manufacture and finish; some of them had additional attachments said to be of great service. The wooden ploughs were also well represented, and quite a number were on the ground. The subsoil ploughs were of almost all shapes, as adapted to loosen the hard under-stratum. Much diversity of opinion prevailed relative to these implements, and considerable ingenuity has been displayed in producing the result said to be arrived at. There are also some double share Trench ploughs, well manufactured articles; and double mould-board ploughs. There are several Gang ploughs, some turning three and some four furrows.

CULTIVATORS, HARROWS, ETC.

The two horse cultivators in iron are excellent articles, and well worthy the farmer's attention. There are many improvements lately made, some no doubt very important; one in particular is that of removing the share and substituting its support so as arranged as to form a strong and substantial grubber, where the land is too hard to allow of the ordinary share being used. There was, however, much praise due to all as most useful implements. Those cultivators manufactured from wood and iron combined seemed to be liked by farmers, but could hardly be as durable as all iron.

There were some horse hoes, for one and two horses, and small gang ploughs used as horse hoes, reversible in their action on the soil. These ploughs were considered very useful as cultivators between corn and potatoes, turnips, &c., &c.

The clod crusher shown we consider is liable to be broken when coming in contact with stony land; otherwise, no doubt, it is an efficient implement.

There were several pairs of iron harrows, and one with wooden "bulls" and steel teeth, said to be a most useful tool and of very light draught. The wooden harrows did not excite much attention.

The wooden rollers were various and fanciful in their construction, adapted to all kinds of uneven surface and rounding land, and so arranged as to turn very easily, many of them being in two or three portions, instead of being formed of one long roller as was the case formerly.

Of grain drills there were three, and all possessed advantages—some in excess of others when used in particular positions and under trying circumstances. There were two seed drills of the ordinary kind used. Those used for sowing plaster were well adapted for the purpose, and saved a great deal of the irregularity that of necessity exists in hand sowing.

MOWING MACHINES, ETC.

In mowing machines and reapers there was an immense show, all excellent in their way, and all claiming something peculiar as adapted for various kinds of work. Some reapers were splendid samples of automatic work, especially those with self rakers, which were so completely under the control of the driver that he could make a sheaf of any given size all day long. The labour-saving of these machines must be immense at the present high price of labour.

RAKES AND PITCH-FORKS.

In horse rakes there was a good show, and several varieties; those with steel spring teeth seemed to be the favourites generally, as less likely to get out of repair.

The horse pitch-fork, for unloading unbound grain and hay, and conveying it to any part of the barn on overhead railways, was very much visited—those who had for years used the old plan being strongly interested in the new, and those who had derived the benefit from the improvement universally approving of the implement.

THRESHING MACHINES.

We next come to the horse-power threshing machine and separator, and here there was a splendid show, with, as usual, many claimants for various improvements. That which seemed specially to please the public was a most excellent adaptation of the position of the separator to the horse-power, whereby the one can be used in any position relative to the other, not necessarily, as heretofore, confined to a right angle or parallel position. This improvement was due to Messrs. Medcalf, of Toronto, and we have no doubt will prove of immense utility and convenience.

OTHER IMPLEMENTS.

In potato diggers there were several shown, one in particular that claimed to possess the power of digging and cleaning the potatoes, and having them all picked up and in a box, and, moreover, thus effectually operating on three acres each day.

There were three stump extractors on the ground, two screws and one lever. All had their admirers, and if the size of the chains used is any guide, their strength at a pull must be immense.

In straw cutters the show was certainly most excellent; many kinds were heavy and strong—strong enough to cut not only the straw, but apparently also the fork used to handle it with. Some exhibitors claim that any small stick that by accident may get into it affords no impediment whatever, so far as breakage is concerned.

There are several smut machines, of excellent construction, and much was claimed for their performances.

The grain-cracker and corn and cob grinder was much approved of generally as among the most useful implements the farmer could possess.

The elaborate clover-cleaning machines are so far in advance of former exhibitions as scarcely to be recognized as an effect of the original conception.

There were several cider mills and presses, and visions of cider and excellent and palatable drinks were manifestly in the minds of the many spectators.

WAGGONS AND SLEIGHS.

The two-horse team waggons, with spring market waggons, were in great force, and numbers of excellent articles were on exhibition. One cart also, such as is used for light purposes, was shown.

In farm sleighs there was little shown, with one exception, which consisted of a combined sleigh, with wheels so arranged that if at any portion of a journey the snow should fail, nothing more was required than to bear down on a handle, and the wheels did the work, to be again raised in their turn if the sleighing was again good.

BRICK-MAKING MACHINES.

There were two brick-making machines on the ground, one in actual work, and it certainly turned out an excellent article with rapidity; the other was not tried at that time, and was only a hand machine, whereas the first named was driven by power and pressed every brick in its turn.

DITCHING MACHINE.

The draining or ditching machine was much thought of. Hitherto the digging of the trench for the tiles has been a great expense, but with this machine there seems to be no doubt that draining can be done wholesale and at small cost.

There was a large show of straw-cutters, which excited much attention, and were arranged for horse or hand power. One of this class of implements was so adjusted as to be used as a pea thrasher, and a conveyer or straw carrier attached formed a most complete addition to it. We understand it works exceedingly well. The single and double horse powers were well adapted for such uses, and combine an exceedingly cheap power with great economy of room.

The Eureka ship pump was much liked, and possessed the great advantage of being constructed so as readily to pump wheat or water from the hold of a wrecked vessel.

The root-steaming boiler, an arrangement for steaming feed for cattle, was constructed of cast iron with corrugated surface; supposed to combine more than ordinary advantages by this formation.

A self-unloading waggon box was shown, and certainly had every appearance of a most useful addition.

In drain tiles there was only one principal entry. This machine is said to make tiles of any size likely to be required, and at the same time capable of turning them out in large quantities. A large assortment of very superior quality was shown.

Messrs. Tuttle, Date & Rodden showed an excellent assortment of scythes, hoes, forks, and other tools, some with additional portions to those usually made, whereby it was believed more than ordinary strength was attained, combined with great neatness of appearance.

The Oshawa Works, as usual, exhibited a good assortment of hoes, forks, scythes, and other tools. This old manufacturing company still retain their character for good tools, as their assortment fully proves.

The fanning mill department was very active. Exhibitors under this head were testing their various mills, with all sorts of apparently impossible performances, such as mixing oats, peas, wheat, and grass and wood seeds together, and at one operation completing an entire separation, leaving the wheat or peas entirely free from all oats or weed seeds. The various smaller seeds were collected, and cleaned, and separated in heaps each by itself. These implements, certainly, have attained to great perfection in cleaning grain. One mill was so arranged with a conveyer for the cleaned grain that it delivered it completely finished in the bag.

Machines for cutting roots for stock were numerous and well represented, and were capable of cutting any shaped piece from simply slicing the turnip to cutting it into dice or pulping it into mash.

Churns were numerous and of all kinds; some were driven by dogs, and seemed to be much admired on that account. There was every motion conceivable given to the cream by the churn, from the ordinary old fashioned dasher to the tumbling bonet churn, which was caused to revolve over and over with great apparent ease to the operator.

The wooden force pumps were in full action, and it was claimed by the maker that he could throw a stream of ⅞ of an inch in diameter from 40 to 60 feet high with the power of two or three men. These pumps were therefore well adapted for farm fire-engines.

In washing machines there was but a miserable show. Whether the machines now on trial and those condemned for inefficiency throughout the country have caused a despairing lull in the manufacture we are unable to say, but certainly there are more condemned washing machines in the country than great successes in the manufacture.

The fruit pickers were of various kinds, and several sorts were shown. There can be no doubt that the introduction of some machine by which our fruit can be picked with less labour than by hand, and at the same time without injury, would be a most useful implement. We export largely to the old countries, and if the fruit is bruised it decays and is valueless.

The horse shoeing brake was a very strong and useful machine, and blacksmiths would do well to have one or more in a village, where accidents can be contended with or operations performed.

Welland Vale Tool Works show some excellent specimens of manufacture in forks, hoes, scythes, and various articles of like nature, some of which, the manure and hay forks in particular, have an excellent additional attachment at the juncture of the handle, whereby great additional strength and extreme neatness of manufacture is obtained.

The St. Catharines Saw Works, amongst a full assortment of saws for ordinary purposes, show a monster six foot eight inch circular saw—a creditable addition to our Canadian manufactures—also, what is claimed to be a champion combination cross and ripping hand saw, so arranged with deeply cut gullet as to greatly assist in the delivery of the saw-dust.

Goldie & McCulloch, of Galt, exhibit mill stones, planing machines, and barrel head turning machine, heading planer, with turbine water wheel; tenoning machine, sash and moulding machine, self acting shingle machine, with vertical saw; cloth press, cloth brusher, carding machine, with steam governor and water wheel governor; measuring and winding machine, used in cloth manufacturing, with indicator attached; wool picker, hard waste pickers, and must machine.

McKechnie & Bertram, Dundas Tool Works, produce a complete assortment of mechanical tools and wood working machinery. Also, tools of various kinds for working in iron—amongst which are four drilling machines, expanding die, and bolt cutter; a compound planer for planing straight and circular iron work; nine foot planer; 14 foot and gap lathe; and complete screw cutting lathe; car wheel borer, for Messrs. Hamilton, capable of boring 40 to 50 wheels per day. This machine weighs 8,000 lbs. Amongst the wood working machines is one for planing, moulding, and beading on both sides of the lumber to be operated on; one pony planer, and machines for sash and door work; shaping machine for all kinds of irregularly formed work; power morticing machine, one specially for car work, and also for ordinary use.

Morrison & Co. show an assortment of steam gauges and brass work; engineer's clock for timing an engine's work and speed; and steam indicator, and test guage for boilers, with an assortment of cabinet brass work.

Sweet, Barns & Co., of Syracuse, N. Y., exhibit mowing machine knives, with sickle bars and sections.

Charles Levy & Co. exhibit a planing and moulding machine, constructed on a new plan, dispensing with numbers of belts, and using worm feeding wheels; also a powerful water wheel, manufactured by Barber & Harris, of Meaford.

ARCHITECTURAL.

John Dennis shows a barn of new construction, the object being to dispense with the ordinary heavy timber used, and to substitute that of a very much lighter description. The principal feature of its construction seems to be that of first building a small barn with exceedingly light timber, and using all the well known strength derived from additional long braces. When this centre erection is completed similar additions are made all round the first, and attached to it there is also a horse power of the old cheap "finger and thumb" motion, said to be strong enough for eight horse power, which drives a threshing and unloading machine for hay and loose grain when unbound. The grain is delivered on a transverse railway arranged in the roof, which conveys its load to any part as required, and on its arrival at any one given point automatically delivers its load and returns for another. The new principle here developed and used, consists of round 2 in. holes being bored, and square 2 inch hardwood pins driven into the piece that would ordinarily be morticed; the other end of the square pins is again inserted into the piece that ordinarily would be tenoned and through each end of this square pin, where the two surfaces of the part of the timber to be joined are brought together, smaller pins of about ¼ of an inch in diameter are driven across, with a little "draw bore," as it is called, which effectually brings all parts into close contact. It will be seen that by this means small hardwood tenons are virtually substituted for the ordinary pin, and can be therefore made much lighter.

GRAIN.

In spite of adverse harvest weather and the various troubles and difficulties that croakers are apt to bemoan so woefully, the appearance of the grain at the present exhibition affords abundant evidence that, in sections of the country widely spread, the quality of the crop has been better than usual. The samples of all the cereals, but especially of wheat and oats, are finer than we have seen them for several years; and in some instances there was an evenness of excellence that rendered it a matter of no small difficulty for the Judges to award the premiums. For the Canada Company's prize of $100 there were more than the usual number of competitors, but the honour was awarded to James McNair, of Vaughan, for a remarkably good sample of Deihl wheat, heavy, plump, and even. The second prize of $50, given by the Association, was gained by John Cullis, of Hamilton Township, for 25 bushels of Soules wheat, and the third to Joseph Freeman, of Flamboro, for the same quantity of the Deihl variety. The first prize for the best two bushels of white winter wheat was to Joseph Redmond, of Otonabee, and the second to W. Taylor, of Pickering. The last-named exhibitor also secured the first prize for red winter wheat, and W. Grant, of Puslinch, obtained the second.

The samples of Fife wheat were particularly good, not only in the section devoted specially to that variety, but in the mixed class, the Fife wheat took all the premiums. The prizes did not go to any particular district, but were divided over the Province in every direction, showing that no section has been specially favoured in the season.

There were some excellent samples of barley, many of which, in spite of the pervading wet weather, were not only plump and well filled, but bright in colour. Of the two-rowed there were six entries, Thomas Gibson, of Markham, taking the first prize. The competition in the six-rowed variety was much greater, and Walter Riddel, of Cobourg, won the laurels.

There was but a small show of rye.

In oats there were a large number of entries, and the samples were unusually fine. Indeed, there was scarcely a bag of inferior ones among them. The judges had much difficulty in making the award—in white oats especially, which were remarkably fine. There were also several bags of heavy and well-filled black oats, the best sample of which was undoubtedly shown by W. Riddel, and gained for him another first prize.

There was less competition in peas, though the samples were good.

Indian corn was fairly represented, the palm going to Niagara in the person of H. J. Brown.

Five bales of hops were exhibited, mostly well cured, and in prime condition.

There was besides a good display of various seeds, though the number of competitors in this class was, as usual, small.

FIELD ROOTS.

The favourable accounts received from all parts of the country respecting the fine condition of the root crops would lead us to expect a good exhibition in this department, and the visitors to the building in which the field products, along with the horticultural collection and produce of the dairy, were effectively displayed, would meet with no disappointment in regard to this part of the show. Whatever the season, we generally see some immense specimens of mangold and ruta bagas; but there is this year a uniformity of excellence, and a larger proportion than usual of fine samples. Some of the monster mangolds were quite curiosities, but such giants are not the most desirable for the farmer to aim after, and medium sized roots are on many accounts the most profitable. There was a good display of the sugar beet, a crop that will, no doubt, be more extensively grown now that the attention of the cultivator has been directed to the feasibility of successfully raising the root and manufacturing the sugar in this country. Of carrots, especially the white Belgian variety, there was an excellent show. In the display of potatoes we did not notice anything very remarkable. Some of the exhibitors would have improved the appearance of their collections if they had taken the trouble to remove the dirt from the tubers. At an exhibition one expects to see at least clean samples. The squashes for cattle and field pumpkins, as usual, elicited exclamations of wonder from the passing spectator.

HORTICULTURAL DEPARTMENT.

FRUIT.

The display in the general list is one of unusual beauty and excellence. The change made in the prize list, whereby those varieties most usually grown throughout the Province were brought in direct competition with each other, had the effect of calling out a most superb display, and made the contest for excellence unusually spirited.

The collections of thirty varieties of apples which were shown were of superior merit, and such was their excellence that the judges, after awarding the three prizes, designated two others of the collections as worthy of high commendation. Also in the collections of ten varieties of apple the same fine quality was manifest; and a fourth one of them was distinguished by a commendation from the judges.

In the collections of four varieties of dessert and four varieties of cooking apples, the competition was very high, and it was only after long and critical examination that the awards of first prize were made to Mr. Gage J. Miller, of Virgil, who displayed much judgment in selecting for the collections varieties of high quality as well as fine samples of fruit.

The samples of Snow Apples placed upon the tables were indeed of surpassing excellence, and long and sharp was the scrutiny to which they were subjected by the judges. This variety usually succeeds best in the northern parts of the apple region, and we see that both the prizes for this variety were taken by gentlemen residing in the cooler sections—the first by Mr. Sam'l. Wood, of Islington, and the second by Mr. John Shuttleworth, of Weston.

The Fall Pippin is still a great favourite, as could be seen by the number of samples exhibited, although in some places it is becoming very difficult to grow it free from spots. It is an excellent apple, and Mr. F. Morrison, of Hamilton, may well be congratulated on being able to grow it in such high perfection as to carry off the first prize.

As an autumn apple of great beauty and excellence, valuable both as a dessert and cooking fruit, and selling in the market for the highest prices, the Gravenstein stands in the foremost rank. The display of this variety was not large, but the specimens shown were of great excellence, and came, so far as the prizes indicate, in best quality from the old Niagara District.

The Ribston Pippin is a very valuable variety, admirably adapted to our climate, growing here in the highest perfection, and commanding, when shipped to the markets of Great Britain, the very highest prices. We are sure the admirers of this fruit at home would have paused in wondering delight over the truly splendid display made in this variety. Though the first prize was given to Mr. Gage J. Miller, of Virgil, who has the advantage of residing in what is termed the fruit garden of Canada, yet the second prize was won by Mr. G. Tattle, of Yorkville, with a sample scarcely inferior, thus showing the adaptability of this fine variety to most parts of the country.

The Spitzenberg, Baldwin, Rhode Island Greening, and Roxborough Russets—four varieties now well known and universally esteemed, were displayed in great force, and of the very finest quality.

The best samples of Golden Russets of Western New York were from the Niagara District, where it has been considerably planted by growers for market, and is gaining a decided reputation as a profitable market apple.

The Swayzie Pomme Grise, one of our most delicious winter dessert apples, has not yet found its way into very general cultivation. The best samples were from Niagara, where it has been long known and highly esteemed. We cannot here refrain from a word of commendation upon the decision of the judges, who evidently were not influenced by size merely, but awarded the prizes to the best developed specimens of the true and normal type.

The Northern Spy is gradually working its way into the esteem of the Canadian fruit growers, if we may judge from the number of plates of this variety and the excellence of the samples. The tree is tardy in coming into bearing, and will not yield its fruit in perfection to the negligent cultivator, but the tree is hardy, and from its habit of putting forth its blossoms quite late, the fruit often escapes a late spring frost that nips its more adventurous neighbours, while in quality for table or kitchen use, and in beauty of appearance, it has few equals.

There was quite a number of seedling apples offered in competition, the most of which, in the opinion of the judges, exhibited no distinguishing quality of excellence. But there were two plates of these which were notable exceptions, and to which the prizes were awarded, the first exhibited by Mr. John Shuttleworth, of Weston, and the second by Mr. W. Forfar, of Agincourt.

Mr. Shuttleworth's seedling bore a very marked resemblance to the St. Lawrence, but when tested with that variety seemed to be a later sort and of a more sprightly flavour. This seedling should be sent to the fruit committee of the Fruit Grower's Association, with a full account of its origin, and the character of the tree, in competition for their premium of fifty dollars.

The collections of twenty varieties of pears and of ten varieties embraced some of our very best and most valuable sorts, but some of those most usually seen at our exhibitions were doubtless ripe and gone some time ago. Yet we never saw finer samples, more even and perfect, than those to which the first prizes were given, and they certainly reflect great credit upon the skill and taste of the worthy President of the Fruit Growers' Association. Were others of our clergy to emulate his example, and seek for rest and refreshment to their wearied mental energies and social sensibilities in the soothing and healthful culture of the fruit or flower garden, they would be much the gainers in bodily health, and their people in better sermons.

Bartletts were too far gone—only two plates, and these fast going to decay, put in an appearance.

White Doyenne has spotted and marked so badly in the United States that it is not much planted now by our neighbours over the border, but the specimens shown here manifest no symptoms of trouble from this cause, and were most noble specimens of this much-valued sort.

No one of our pears seems to be so widely adapted to the various parts of the Province as the Flemish Beauty. The tree is very hardy—one of the most hardy, and the fruit is both of large size and fine quality. The plates shown are very fine indeed, and fully sustain the high reputation of this pear for beauty and quality.

The Louise Bonne de Jersey is a variety so productive, and of such pleasing appearance, that it has become a general favourite, notwithstanding that it is not of the very highest quality.

On the other hand the Belle Lucrative is a fruit of the highest quality, but has been so little cultivated that only two plates were shown for this variety, and of these only the one shown by Mr. John Sharman, of Oakville, was the Belle Lucrative.

If greatness be a quality of goodness, then surely the Duchesse d'Angouleme on exhibition are of the highest degree of goodness. We heard one of the most experienced of the judges in this department remark that he thought he had never seen such monstrous pears. Mr. Robert Stibbard, of Eglinton, who bore off the palm, should tell his less fortunate brothers in fruit culture how he grows such monsters.

Were the tree of the Beurre Bosc only a little more hardy, we are sure it would soon become a favourite sort. In symmetry of form, fine cinnamon russet colour, and rich, juicy, spicy flesh, there is nothing to be desired. There are not many plates exhibited, and the two prizes are taken by Niagara, where probably it finds its most congenial climate.

Beurre Clairgeau will doubtless be found to thrive and fruit well over a larger portion of the country; for we find that Mr. George Murray, of York Township, carries off one of the prizes. It is comparatively a new sort, but one which will probably find favour on account of its fine size and appearance.

It is too soon to get many specimens of Clapp's Favourite, for which a prize was offered, but no samples appeared on exhibition. This new variety has been very highly commended, and is well worthy of a trial at the hands of lovers of good fruit, and it has been well done to draw attention to it by the offer of a premium.

Winter Nelis is one of our very best winter sorts, and the samples shown are of the highest excellence. It succeeds well over a large part of the country, which might be inferred from the fact that the first prize was taken by Mr. W. A. Smith, of Brantford, and the second by Mr. J. Young, of Hamilton.

The mysterious pear blight seems to be particularly fatal to the *Glout Morceau*, but the specimens here shown demonstrate that the trees do sometimes live and bear most noble samples of this fine winter pear.

The Vicar of Winkfield is another of those very productive kinds which have been a good deal disseminated, and if ever well developed specimens could be a guarantee of fine flavour, these should secure that very desirable quality; but the sort is one of great fickleness, bringing to mind Virgil's description of woman, *"varium et mutabile semper femina."*

In any other variety of fall pear the competition was very spirited; but Mr. W. R. Warren, of Niagara, distanced all competitors with a plate of the very finest Seckels—a variety that has no peer for quality; and Mr. R. Burnet, of Hamilton, justly won the second with fine samples of Beurre d'Anjou—a variety that promises to be one of our most valuable late sorts.

It is too late in the season to expect a good display of plums; hence, although the crop in many places has been very fine this season, the number exhibited is quite limited. One exhibitor, with commendable zeal, has endeavoured to preserve a number of varieties beyond the period of ripening for the purpose of exhibiting them, but the acid preparation in which they were kept so destroyed the flavour that the judges could form no opinion of their quality beyond their size.

What is true of the plums is also to be said of the peaches—the time of the Exhibition is too late for any display of good peaches. A few are shown, but they are, like all late peaches, lacking in richness, sweetness, and delicacy of flavour.

The display of grapes grown in open air is large, and gives evidence of increasing attention to the cultivation of this fruit. The number of varieties is constantly increasing, and quite a number have been found to be every way reliable in our climate. There were some thirty varieties shewn by Mr. James Taylor, of St. Catharines, who has paid no little attention to the cultivation of the grape, and exhibits samples of great size and beauty, which received the first prize.

The Concord variety is shewn in considerable quantity, and is evidently succeeding over a large part of the country. The vine is hardy, and a very abundant bearer.

There were a good many plates of the Delawares shown also, one of the sweetest grapes grown successfully in the open air. The prize samples came from Niagara, and were most beautifully ripened.

It is too late to expect many samples of the Adirondac, which is an early ripening sort; but the prize sample, shown by Mr. Thos. Brownlie, of Scarboro', proves that it can be well grown on the north shore of Lake Ontario.

The Diana has now been quite extensively disseminated, and it is gratifying to find that so good a grape is grown, and ripened in such perfection, in Toronto and York Township, that the grapes from this locality carried off both prizes. It is said to be an excellent variety for the manufacture of wine, and that the prize wines was made from this grape.

The Creveling is a very early ripening sort. The prize samples came from St. Catharines and Scarboro, showing that it thrives well in quite different localities. The fruit is of fine quality, but the vines do not always set well, thus often giving the bunches a very loose and straggling appearance.

The Hartford Prolific is also early, and evidently grows well in Scarboro and at Goderich. It is hardly equal in quality to either Creveling or Adirondac.

A large number of the Rogers Hybride were shown. These are very large in berry, not uniform in bunch, most of them quite hardy and ripening in good season. The best bunches of Rogers, number 19, came from York Township, which shows that some will thrive over a large part of the Province.

The Catawba will not usually ripen well in Ontario, but Mr. Durand, of Niagara, exhibited three clusters of this variety that fully equalled any, even the best we ever saw, from the famed islands of Lake Erie.

The Iona is comparatively new, and many fears are entertained lest it should not be found to thrive in most parts of the Province, but Mr. J. B. Hay, of Waterdown, exhibited some very well-ripened clusters.

There are but few plates of grapes grown under glass in the general list, but the few that are shown are of fine quality. It is to be hoped that our residents in those parts of the land where the finer out-of-door grapes cannot be thoroughly ripened will avail themselves of the hints given in the *Canada Farmer*, upon the cheap construction of glass houses, and enjoy the comfort of delicious grapes grown under glass.

There is a considerable display of water melons, and some green and scarlet flesh melons, but in October they cannot be of a very fine quality.

There were a few entries of domestic wines, but it was evident that very few yet understand the art of making wine from grapes. The dry wines on exhibition were almost sweet, and most of the sweet wine would pass for a cordial. Yet it is only by continued attempts that success can be achieved, and there is no reason why wines of excellent quality should not be made here. The prize offered for the best essay on wine making is a judicious action on the part of the Agricultural Association, and if continued for a few years will furnish our people with the much needed information on this subject.

In the professional list there is a very fine display of fruit of every sort, in which Mr. Leslie's, of Toronto, nurseries are most prominent, ably followed up by by J. A. Bruce & Co., of Hamilton; James Dougall, of Windsor; D. W. Beadle, of St. Catharines, J. & J. Gray, of Toronto; Chas. Arnold, of Paris; and C. E. Woolverton, of Grimsby. The country owes much to the enterprise and labours of these gentlemen in the distribution throughout the Province of such excellent and truly valuable and profitable fruits.

The collection of fruits shown by the Hamilton Horticultural Society, to which was awarded the first prize, is a truly magnificent display of all kinds of fruit, contested keenly by the Galloway Club of Lincoln County.

The display of garden vegetables of all kinds was large, and gives evidence of increasing interest and attention in this department of horticulture. A liberal variety of garden vegetables should be enjoyed by every well-to-do farmer, yet we venture to say there are very many who give no attention to the cultivation of the garden.

The celery exhibited is good, the onions as handsome as any could wish, and tomatoes and capsicums in greatest profusion. We noticed that in winter squashes the variety known as the Hubbard carried off first, second, and third prizes; and the first prize for the best six varieties of patatoes for table use was given to Garnet Chili, Early Goderich, Ash-leaved Kidney, Breeze's King of the Earlies, Breeze's Prolific, and Early Rose.

There was nothing of much interest to be fonnd in the floral department, unless we except some really beautiful dahlias, in which Messrs. Leslie & Sons take the lead. Of these we name Lady Hubert, Queen Mab Bird of Passage, Peri, Stafford's Gem, and Triumph, as being very fine indeed. It can be no matter of disappointment that the display of flowers should be limited; the only wonder is that the frosts had not cut them down out of doors, so that the only resource would have been in greenhouse plants.

In closing this hurried sketch of the horticultural department of the exhibition, we can truly congratulate its friends on the continued evidence of progress, and an ever increasing taste among the people for, and skil in the cultivation of these finer products, for which so large a part of the Province is most admirably adapted.

DAIRY PRODUCTS.

The new stimulus that has been given to dairy husbandry during the last few years by the introduction of the factory system, has called forth a large amount of enterprise and skill, and in various sections of the country, east and west, new establishments, are springing up, while the increased competition and the refined requirements of the English markets are stimulating the pioneers in this manufacture to bring up the quality of their production to the highest possible pitch of perfection. Judging by the factory products shown at the exhibition, we expect to learn that the quality of Canadian cheese during the past season has been of superior excellence. There was considerable competition; and the districts represented were widely spread, but chiefly in the counties of Oxford, Hastings, Northumberland, York, Halton, Haldimand, Welland, Perth, Huron and Orey. The general excellence of the samples was so good that the judges were very slow in making their election, and we believe did not come to a decision till after an adjournment. It is quite certain that some of the cheeses not honoured with a premium card were of a quality that reflected great credit on the maker. Our own judgment would even have given a first prize to one of this undistinguished lot. The prize cheeses, were, however, without doubt, excellent samples. A. McBean, of Galt, Platt Kiernan, of Haldimand, and T. Ballantyne, of Sebringville, carried off the honours in the order of their names.

The private dairy cheeses, though not so numerous, made a creditable display, and were mostly of prime quality. A. Shaw, Nissouri, J. Patton, Scarboro', J. Franks, Dorchester, and A. Glendinning, Scarboro', were the successful exhibitors. Mr. Shaw also took a first prize for Stilton cheese; and Mr. Parsons, of Guelph, took only a second, though it would be difficult to find a better article than the cheese of his make.

The competition in butter, and the quality of much that was exhibited, gave evidence, which ought not to be confined to these rare occasions, that good butter can be made in Canada. Six prizes were awarded in each section, and the judges felt constrained to distinguish others as worthy of a premium. Let the unfortunate consumers who have suffered from dyspepsia and nausea, or deprived themselves of the luxury of butter because a good article was not to be had, consult the prize list and take courage.

APIARY DEPARTMENT.

Bee-hives, bees, and honey, were well represented, showing clearly a great interest in bee culture. There were six competitors in bee-hives. Most of the hives, though constructed on the movable comb principle, are somewhat small. B. Losee, of Cobourg, showed a hive with a wire bottom, underneath which is a drawer for catching the moth, dirt, &c. If this is not kept quite clean it will prove detrimental to the hive, and become a moth nest instead of a moth trap. The frames of this hive come in contact with each other down the entire sides, and it must be difficult to operate without killing bees.

Mr. P. Nicolls, of Lindsay, showed what he calls the Economic Hive. The frames are hung with metal bearings, so constructed as to hold the frames at equal distances apart It has an internal arrangement, which, by means of a crank, is forced against the panes to hold them in place, or by withdrawing the frames may be moved apart. This in many cases would be difficult to do.

D. A. Jones, Tecumseth, exhibited Jones' Perfection Hive. The hive proper is made of tin, which is encased with wood. The frames are very deep, and for that reason difficult to handle when filled with honey.

J. Munson, of Collingwood, also showed the Dominion Beehive. It is much upon the same principle as the Langstroth hive, as improved by H. Alley, of Wintram, Mass. It is constructed with side and top drawers for surplus honey. Like the Langstroth it is very heavy and cumbersome, and like the Economic hive it is expensive.

J. H. Thomas was also on hand as usual with his hive, which is too well-known to require description. He also exhibited two fine stocks of Italian bees, and an Italian queen in an observing hive.

A. C. Attwood, of Vanneck, Middlesex Co., also exhibited J. H. Thomas's hive, as he claims, improved by himself. Mr. Attwood also exhibited a movable bee palace for exhibition purposes, which is very tastefully constructed, and in every way convenient.

It is gratifying to see a growing interest in this branch of rural economy. Nearly every year new hives are brought out claiming attention, but in most cases they are too complicated and too expensive.

NATURAL HISTORY AT THE PROVINCIAL EXHIBITION.

Were the progress of natural science in Canada to be measured by the display in this department at the annual exhibition, sorry indeed would be the estimate formed of the labours of our naturalists and the capabilities of our country. Those, however, who possess collections in the various classes of zoology and botany, know better than to expose their precious treasures to the dust and dirt of the exhibition, and the manifold hazards of carriage to and fro, when the only compensation they can look for is the few paltry prizes offered by the Association. If the Association desires to afford to its visitors a representation of the fauna and flora of the country, let it offer more suitable prizes and ask for collections of a more special character; and let it also set apart a certain portion of its space for the fitting arrangement and display of the specimens. In these days, when some men devote the labours of their lives to the working up of a few families in a single order of the animal or vegetable kingdom, it is absurd to ask for such general collections as would require a whole museum to illustrate.

Last year, at London, there was a very creditable display in the department of Zoology, thanks to the local branch of the Entomological Society; but this year there is not a single insect on exhibition, not a single mammal, not a reptile, not a shell, not a fossil, not a mineral. The only entries are—in Mithology—a fine case of stuffed birds, chiefly water-fowl, very prettily gronped about a bit of marsh, with artificial water, rocks, ferns, lilies, etc,; it is contributed by Mr. J. Sand, of Toronto. A number of cases of both Canadian and foreign birds by Mr. S. Herring, taxidermist, Toronto, among which we noticed particularly some English game birds, such as quail, pheasants and partridges; a pair of East India pheasants, California quail, bitterns, a large case of owls, ducks, gulls, hawks from various parts of the world; another of herons and other birds; others of ducks, snipe, &c,—the whole well mounted and carefully preserved. In Botany an excellent collection of Canadian plants by Prof. Macoun, of Belleville, comprising no less than 1565 species, viz. of exogens 735, endogens 381, acrogens 79, and anophytes 320. A collection of Canadian ferns by the same exhibitor, who is well-known as one of the best botanists in the Dominion. A very fine and well-prepared collection of native medicinal plants and roots also by Prof. Macoun. A neatly-prepared collection of Canadian plants by Miss Marton, of Guelph. The only other entries in natural history were by Mr. S. Wilmot, of Newcastle, who exhibited a series of aquaria stocked with salmon in their different stages, white-fish, and speckled trout all of his own rearing, and also the breeding apparatus filled with salmon

ova. This is certainly one of the most interesting and valuable portions of the whole exhibition, and many thanks are due to Mr. Wilmot for the amount of trouble that he has taken in bringing up so cumbrous an apparatus for the edification of visitors. His success in this somewhat novel branch of industry has thus far been very encouraging. Less than four years ago he began with four salmon; this year he has sent out from his ponds no less than 250,000 young fish. We trust that his good example will be widely followed, and that in a few years all our rivers and streams may be stocked with fish, and salmon become as cheap and abundant as they were in the days of the first settlers.

Annual Meeting of the Agricultural and Arts Association.

The annual meeting of the Directors of the Provincial Agricultural Association was held on Oct. 6th in the Agricultural Hall. There was a large attendance, not only of delegates, but of visitors from various parts of the Province. Hon. David Christie, the President, occupied the chair.

The President in his address adverted to the prosperous condition of the agricultural interest, and the happy continuance of peace in this country. He referred to the success of the present exhibition, and gave the financial statement of the year from the 1st of January to the 20th September, as follows:—

RECEIPTS.

Balance on hand 1st Jan., 1870	$1,649 97
Prizes unpaid and returned	12 00
Miscellaneous sources	791 54
Rents of Hall and shops	900 00
Government Grant for 1870	10,000 00
Rents for Booths to date	1,510 00
	$14,843 51

PAYMENTS.

Salaries	$1,328 32
Board expenses	1,206 75
Miscellaneous (payment to Glackmeyer, $1,000, etc)	1,397 87
Printing and Stationery	595 84
Legal expenses	229 19
Exhibition	229 00
Prizes	13 00
Veterinary School	550 00
	$5,544 97
By balance	9,298 54
	$14,843 51

He vindicated the management of the Council, and deprecated any transfer of power from that body into the hands of Government. He then very appropriately set forth the advantages of agriculture as a pursuit, and in the course of his remarks on this subject observed:—"My conviction is that we have lessened, *most materially*, the *grain-producing* power of the country, by the excessive drain which we have made on it for so many years. There can be no question that the most direct and economical recuperative process is in increasing the number of acres of grass, and diminishing the number of acres of grain—in other words, by *more* and *better stock*, and *less grain*. After all, I should not say that the result will be *less grain*. The acres in grain would be fewer, but the gross product would be much larger, while we should have more beef, mutton, and pork, and of better quality. It is also of the greatest importance to economize food for stock as much as possible, because *labour* is *money*, and labour costs a good deal of money in Canada. There are *two* ways of doing this—by improving the quality of the stock, and by economy in the mode of giving them their food. Some years ago I was much struck with the truth of a remark made by a farmer at a meeting of a farmers' club in Yorkshire The subject under discussion was the kind and quality of stock which farmers ought to keep. He said, "*I cannot afford to keep inferior stock, it is too expensive.*" This is true to the letter—inferior stock is too expensive to be profitable; that is, food, which has cost a great deal to produce it, is given to animals which, from their nature and conformation, give the poorest possible returns: there can be no economy in that. I do not wish to be understood as insisting that every farmer ought to keep a thoroughbred herd; that is a business by itself, for as Thomas Bates once said with entire truth, "There are twenty men fit to be premier for one that is fit to be a breeder;" yet, every farmer who breeds cattle, or sheep, or pigs, ought to have pure-bred males, and to use no other if he can get them, because it is only in this way that he can cheaply raise animals which will give the largest return for the food they get. Much may also be done in the way of economizing food by the mode in which it is given. Of course food will go much further when it is prepared in such manner as will give the digestive organs as much aid as possible, such as by cutting and steaming, and by crushing grain, etc.; but I specially refer to a practice which is becoming more common than it was, namely, giving stock a portion of grain or other condensed food while on pasture, and by soiling. Many recent experiments have been made which show that a very large saving can be effected by this process. The most extensive Canadian experiment has been made at Bow Park. Mr. Brown has expressed himself to me in terms of high commendation of this mode of feeding, as proved by his experience; the results of which, it is to be hoped, he will make public.

"When I had the honour on a previous occasion (15 years ago) to address you, I alluded at some length to the great necessity for more thorough and systematic agricultural education So much does want of it still appear to me to be urgent, that I feel it to be my duty again to refer to the subject. The question is, what can be done to supply the deficiency? We have an agricultural class in University College, and an able, experienced teacher, but few students. My conviction is that the work must be more radical: it must begin in our common schools; that is, elementary agricultural and mechanical instruction should form a leading part of the teaching. Dr. Ryerson has published a valuable little work on agriculture, which I hope to see made a text book in all the rural districts. Unquestionably, the result of giving elementary instruction would be not only to impart much important scientific and practical knowledge, but to make the farmers' sons of the country feel the importance and dignity of the profession of agriculture. Dr. Ryerson has done good service to the country by compiling the manual to which I have referred, and I hope that he will see to it that the benefit which it is so well calculated to confer shall not be lost to the country. It is a good thing for the cause which we desire to promote that we have so able a coadjutor as the Chief Superintendent of Education. I feel convinced that he will soon make agricultural and mechanical instruction a leading feature in our common school teaching."

The next topic taken up was the Veterinary College, in reference to which the proceedings of the Council and the reports of the institution have been already published.

The grant to the Entomological Society was mentioned, and the address concluded with some observations on the change in our own tariff, by which live stock for the improvement of breeds is to be admitted free of duty. He lamented, however, that our American brethren had not reciprocated the action

A vote of thanks to the President for his able address was passed unanimously.

The question of the next place for holding the Exhibition was then discussed. A large number voted in favour of Ottawa, but a majority of 77 against 51 decided in favour of Kingston

Fruit Growers' Association.

ANNUAL MEETING.

The Fruit Growers' Association of Ontario held their annual meeting in the Agricultural Hall, Toronto, on Tuesday evening, October 4th, 1870.

President Burnet occupied the chair. The Secretary read the proceedings of the last meeting, which were approved.

The Directors' Report was then submitted, which contained the discussions of the meetings held at Brantford, Hamilton, London, and St. Catharines; the Prize Essay of W. Saunders, Esq., of London; the report of Mr. Saunders on the rewards offered for the capture of curculio; the report on the distribution of the Eumelan Grape; the returns received to the questions issued; an account of the fruit received from the Fruit Growers' Society of Nova Scotia; and the circular, embodying the objects and benefits of the Association.

The Treasurer's Report was then read, showing—

Balance in Treasury since 20th Sept., '69	$ 318 64
Members' fees since 20th Sept., '69	881 00
Government grant, August, 1870	250 00
Total	$1,049 64
Disbursements since 20th Sept., '69	860 41
Balance	$ 189 23

The President read his annual address, which was listened to with deep attention.

Mr. Saunders, of London, moved, seconded by Mr. Ross, of Goderich,—That the thanks of the meeting be tendered to the President for his very interesting and able address, and that he is requested to furnish the Association a copy for publication in the proceedings, which motion was carried with applause.

The meeting then proceeded to the election of officers, with the following result:—

President—Rev. R. Burnet, of Hamilton.

Vice-President—Mr. J. C. Rykert, M.P.P., St. Catharines.

Secretary-Treasurer—D. W. Beadle, St. Catharines.

Directors—Messrs. Jas. Dougall, Windsor; W. Holton, Hamilton; W. H. Mills, Hamilton; W. H. Boulton, Toronto; A. B. Bennett, Brantford; Geo. Leslie, jr., Toronto; W. Saunders, London; A. M Ross, Goderich; and Chas. Arnold, Paris.

Auditors—W. L. Copeland, St. Catharines; and W. J. McCalla.

Notice of motion to amend the Constitution of the Association, so as to separate the offices of Secretary and Treasurer, having been given by Mr. Mills at the Brantford meeting,

Mr. Mills brought the motion forward, and explained that his object was to secure to the Society greater checks upon the funds than could exist under the present arrangement, and not that he had any objections to urge against the person who had held the offices of Secretary and Treasurer.

No person seconding the motion, it was withdrawn.

Miscellaneous business now being in order,

Mr. Hammond, of Credit, asked how the Association classed the Ribston Pippin, whether as a fall or winter apple.

Mr. Dougall, of Windsor, replied that its season of maturity depended upon the place where it was grown; that in the varied climate of our Province—embracing the long, warm summers of the South of Essex, and the short, cool seasons of the Muskoka District—the Ribston Pippin was in the former an early fall apple, quite dry and mealy now, and in the latter was a winter apple, keeping well until March.

Mr. Leslie, of Toronto, said that it varied much also with the warmth of the summer, in some seasons ripening up early, and in other and cooler seasons ripening more slowly and keeping much later.

Mr. Caldwell, of Galt, stated that the apple kept well until March in that section, and was truly there a winter apple.

Mr. Arnold, of Paris, asked what are we to do in judging when the apple is entered both in the fall and winter varieties? and suggested that the method of classification now in use should be abandoned, and that prizes should be offered only for the best samples of particular kinds, without reference to their season of ripening, so that the judges would have to determine which was the best sample of Ribston Pippin, or Snow Apple, or Greening, and not which was the best fall apple or winter.

Mr. Beadle stated that, thanks to the efforts of the President and Vice-President, a beginning had been this year effected in this direction, which it was to be hoped would be carried out in all the departments of the fruit list.

Mr. Rykert stated that as soon as the Board of Agriculture should place sufficient prize money at the disposal of the Committee having in charge the Horticultural department of the prize list, this much needed reform would be effected.

Mr. A. M. Ross, of Goderich, wished to know the cause and cure of the rot in the fruit of the plum. He had suffered much from this rot during the past season, much more than from the curculio, and deemed the rot a far more serious obstacle to the successful culture of the plum than the little turk.

Mr. Saunders, of London, had also suffered severely from this rotting of the fruit, but could not suggest any remedy.

Mr. Dougall, of Windsor, had taken pains to have all the rotting plums carefully gathered and thrown on the ground, and then covered them and the ground under the plum trees with quicklime, also dusting quicklime freely through the tops of the trees, and thought he had in this way been successful in putting a stop to all further spread of the disease. He believed that this rotting was caused by minute fungi fastening on the fruit and developing there, and that the quicklime destroyed the fungus. The rot could not have been caused by the weather, for there had been no rain there for three months.

Mr. Mills, of Hamilton, thought that the rot was not caused by a fungus, but that the rot having begun, and the state of the atmosphere being favourable to the growth of this fungus, it found in the rotting portion of the plum a favourable place for its growth and development. He thought the rot was caused by warmth and moisture occurring at a certain stage of the growth of the plum; and when this did not occur at that particular stage the rot did not occur, hence the plums in some seasons escape the rot altogether.

Mr. Ross said that last season was very wet, and the fruit on only two of his plum trees was affected by the rot, and these were shaded by other trees; this year the rot spread from those affected last year to the trees adjacent, while the trees in another part of his garden wholly escaped; hence he thinks that the rot is infectious in some way, and that if once introduced, if no way of stopping it can be discovered, it will continue to spread until the fruit on all the trees in the vicinity is affected.

Mr. W. H. Boulton, of Toronto, said that the fruit on trees standing in the open ground in his garden was not affected, but on trees at the south side of a board fence the plums had rotted very considerably.

Mr. Arnold, of Paris, believed it to be an infectious fungus, which under favourable conditions grew upon the fruit, causing it to rot.

Mr. Saunders, of London, asked why some of the plums on his trees should be rotten and others near not at all affected, if the cause of the rot be an infectious fungus?

Mr. Arnold replied that he had not observed such a state of things, but that the rot spread to the plums adjacent.

Mr. Mills, of Hamilton, did not think that the rot is caused by fungi; and that the reason why some plums on the tree escaped while others rot is in the difference in the texture of the skin of different plums on the same tree, and that those having a skin whose texture resists the influences of moisture and heat escape the rot.

[Note by the Horticultural Editor—Gentlemen in this discussion made use of the term "infectious fungi;" but they did not mean to be understood as using that term in the usual sense of the word, "*infectious*." Fungi increase by means of minute spores, which are perfected under favourable conditions in a very short time, and in countless millions. These spores are very minute, float in the air, and are carried about by the lightest currents, and these falling on a surface suited to their growth, under conditions of moisture and heat favourable to their germination, soon develop into a perfect plant, again perfecting its spores, to be in turn carried by currents of air and deposited upon some spot where they may germinate and perfect themselves.]

The President announced that the next order of business was the discussion of the subject of fruit culture in its relations to the farming interests of the Province.

Mr. Mills stated that as the hour was getting late, now half-past nine, he would move that the discussion of this subject be postponed, and that the meeting do now adjourn.

This motion was carried, and the Association adjourned, to meet in the city of Hamilton, at the call of the President.

Ontario Beekeepers' Association.

ANNUAL MEETING.

The annual meeting of the Ontario Beekeepers' Association was held in Victoria Hall, Toronto, on the 5th. The meeting having been called to order by Rev. W. F. Clarke, President of the Association, the minutes of the last meeting were then read by the Secretary and approved, after which a few very appropriate and interesting remarks were made by the President. The meeting then proceeded to the discussion of the following questions:—Is there any danger of stocks having too much honey for wintering well? It was decided that there is not. What is the true principle of ventilating stocks in the winter, and how may it be secured? After a somewhat lengthy discussion it was decided that the true principle of ventilation consists in retaining the heat, but allowing the moisture to escape. In what respect are the Italian bees superior to the black bees? After a pleasant discussion it was decided that they were more prolific, more inclined to swarm early, hardier and better honey gatherers.

The officers were then appointed for the ensuing year as follows:—Rev. W. F. Clarke, President, re-elected; J. H. Thomas, Vice-President; A. C. Attwood, Secretary and Treasurer; Executive Committee—H. M. Thomas, D. A. Jones, G. Bennett, B. Losee, D. M. Beckie

The meeting was then adjourned, to meet again on Thursday evening in Victoria Hall, Melinda street.

SECOND DAY.

In the absence of the President the meeting on Thursday evening was called to order by the Vice-President. The meeting proceeded to discuss the following questions:—

Which is the most profitable way of disposing of late or weak stocks? It was decided it was best to take them up.

The opinion was generally expressed that the honey extractor was likely to come into general use among bee-keepers.

After considerable discussion it was decided that it was doubtful whether artificial impregnation could be reduced to successful practice.

After much discussion it was unanimously decided that in ordinary seasons it is unsafe to take honey from the body of the hive later than the first of July.

No decision was arrived at on the question, What is the best plan to prevent swarming?

Have any cases of foul-brood been discovered? It was answered that four cases had been observed.

Do queens mate more than once, and are queens ever partially impregnated? After some discussion it was decided in the affirmative.

The meeting then adjourned, to meet again at the time and place of the next Provincial Fair.

Quebec Provincial Exhibition.

Montreal was favoured with superb weather for the grand attractions of the Show week, and it was fortunate that the great boat race at Lachine did not take place till after the principal days of the Agricultural Exhibition; otherwise it is to be feared that on an occasion of such peculiar interest, aquatics would have robbed agriculture of a very large proportion of her votaries, and the crowds that thronged the Show grounds at the base of Mount Royal would have been found on the river side at Lachine. As it happened, there was ample opportunity on Tuesday and Wednesday (Sept. 13th and 14th), for the public to view the very excellent Exhibition with which the Quebec Board of Agriculture have inaugurated the new Fair Grounds at Montreal. These grounds are situated north-west of the city, and comprise an oblong area of about 21 acres. The land was but recently purchased, and was in a very rough condition. The preparatory work of draining and levelling has been done, the whole has been fenced in a substantial manner, and temporary structures have been erected for the Exhibition. These will be replaced by more permanent buildings for future shows. The horse sheds occupy one side of the grounds, along its whole length; and a similar row of covered stalls have been provided for cattle on the opposite side. In the centre of the ground is a building forming three sides of a square, for the Industrial department; south of this long sheds have been erected for sheep and poultry, and to the back similar structures were set apart for swine.

On the whole the exhibition of the present year compared very favourably with that of 1868, and in some respects showed marked improvement. Taking the live stock in the order of the Prizo List, the Horses claim precedence, and this class was well filled. There were altogether a large number of entries, (nearly 200,) and many animals of superior merit. The competition was mostly confined to stallions, which were consequently in great force. The principal breeds represented were Clyde, Percheron, Normandy, Suffolk and Canadian. Among the first there were some splendid specimens of great weight and power, and well calculated to give a good frame and muscular development to the agricultural horse. The Percherons seem to be coming into favour in the Province, and might with advantage be introduced into Ontario. They are powerfully built, mostly grey in colour, of good size and great strength, with a marked do-

cility of temper, and greater quickness in action and pace than the Clydes. A fine specimen of this breed lately imported by Mr. Wright, of L'Assumption, gained the first prize. The Beauharnois Agricultural Society also showed fine specimens of both breeds. The Canadian horses, of which there were several good examples, present a close resemblance to the Normandy horse, from which they originally sprung. There was a magnificent Suffolk horse (Duke) on the ground. The animal is now owned by the Huntingdon Live Stock Importing Society, but was imported from England by Mr. Cochrane. There was a fair show both of heavy and light draught stallions, and a goodly array of colts and fillies of the general agricultural variety. One of the principal attractions of this class was a very fine "coaching stallion," imported from England by Mr. Hyndman, and now owned by the Huntingdon Live Stock Importing Society. He is a superior animal, dappled brown with black joints, seems full of power combined with activity, and looked the beau ideal in form, speed, style, and action of a carriage horse.

The Cattle class comes next in order, and formed a main feature of the Exhibition. Mr. Cochrane was, in every sense of the term, the principal exhibitor, and showed nine of his recently imported animals. These, though not the choicest of his herd, are really magnificent specimens of the Shorthorn breed. The lot shown by him, consisted of a two-year old bull, "Old Sam," and a one-year old bull, "Star of the Realm," two Booth cows, "Lady of the Lake" and "Jessie Hopewell," and one of Bates' strain, named "Potentilla;" two heifers, (two-year old) "Lady Highthorn" and Baddow Rose;" a yearling heifer, "Phillis IX," and a bull calf. Some of the above had but just arrived on the continent, after a calm and prosperous voyage, which they had weathered without the slighest injury. Among the last arrivals was the famous cow, "Lady Grateful," for which Mr. Cochrane paid Mr. Booth the unprecedented sum of 1,500 guineas. This was too valuable an animal to expose to the risks of travel and showing, but those on the ground were of such a high order of excellence as may well prove to the Canadian breeder what may be attained by careful breeding.

The Ayrshires were most numerously represented, and appear to be growing in favour in the Province. There were over a hundred entries of this breed, and perhaps not a poor one amongst them. Taking them altogether, they were the finest lot that have been exhibited in Canada. The first prize bull, "Mars," owned by Mr. J. L. Gibb, is as perfect a specimen of the breed as can be desired, and cannot be exceeded on the continent. A considerable number of these Ayrshires were quite recent importations, and one of the best was literally transferred from the ship to the show-yard. Messrs Gibb, Whitney, Dawes, and Irving, the gentlemen who have most largely imported this valuable breed into the country, deserve great credit for their spirit and enterprise. For dairy purposes exclusively, Ayrshires are, without doubt, the best unmixed breed.

Of Herefords there were but 7 entries, and a very fair lot. In fact this breed scarcely ever fails, wherever shown, to hold the first rank, as regards evenness of quality, amongst individual specimens.

Devons were but scantily represented, there being but eleven entries, and these, with the exception of the prize animals, were of very inferior order.

The Galloways were represented by just four specimens not deserving any special notice. The breed, valuable chiefly for its hardiness, is evidently not in favour.

Mr. Sheldon Stephens showed a lot of 21 Jerseys, very beautiful animals—4 bulls and 17 cows and heifers, of all ages. The original importation was made two years ago, and the herd has largely increased in the interval. The best were purchased from Prince Albert's farm. They were erroneously classed as Alderneys. It would be well for agricultural societies to include the Jerseys, Alderneys, and Guernseys together, under the name of Channel Island cattle, in order to prevent confusion.

There were two prizes offered for the best herds of cattle, comprising one bull and 5 females, of any age; the first, or Prince of Wales' prize, being $60, and the second, by the Bureau of Agriculture, $50. The Prince's prize was awarded to Mr. Cochrane for a herd of Shorthorns, consisting of Old Sam, Lady of the Lake, Jessie Hope well, Potentila, Baddow Rose and Lady Highthorn: the second was awarded to a herd of Ayrshires.

The sheep classes were tolerably well filled, especially that devoted to Long-wools other than Leicesters or Cotswolds. Of Cotswolds there was a capital show, including many fine animals either imported or bred by Mr. Cochrane; among them a magnificent Shearling ram, which deservedly attracted general admiration, and a pair of ewes that took the prize at the Royal Agricultural Show this year. The Leicesters and Southdowns were of less account, but the class of Long-wools as a whole showed to advantage, with many fine cross-bred specimens of an admixture of Leicester and Cotswold blood.

Of the swine, it would not perhaps be too much to say that it is not often that a better class of pigs is met with than the Suffolks and Yorkshires shown here. They monopolised the lion's share of 118 pens; the Berkshires making a numerically small remainder. Some recent importations shewn by Mr. Cochrane were among the choicest of the class.

There was a tolerably fair show of poultry, well accommodated as to shelter, and rather better arranged as to varieties than in former exhibitions; but they would have shown to greater advantage in uniform pens, which can only be secured when provided by the Directors of the Exhibition, instead of being left to the fancy of the exhibitors. Mr. Stephens' Dark Brahmas were excellent birds.

The display of implements was not large, but possessed some special features of interest. One thing worthy of note was the number of implements shewn by the firm of Evans & Co., who have, what is much wanted in the principal cities of Ontario, an Agricultural Implement store, where the farmers can procure almost anything in this department, instead of being obliged in every case to ascertain the name and locality of the manufacturer, and obtain the desired article from him. This has been often felt as a serious inconvenience in Ontario. A double-furrow plough may be mentioned among the novelties. Much interest was also manifested in a brick machine in actual operation. Judging by the expeditious and capital work turned out, it has every promise of being a most useful invention. The patentees and exhibitors were Messrs. Bulmer and Sheppard, of Montreal. The machinery appears simple and effective. The prepared clay is fed at the top, well worked and mixed within the apparatus, and pressed into moulds at the bottom. The bricks are turned out six at a time, every few minutes, perfect in shape and solidity. A man carries away each tray as it is delivered, and replaces it with an empty one. Two men and three or four boys are all that are required to attend to the machines. It is said to be capable of turning out 15,000 bricks a day. The amount of pressure can be regulated with the greatest nicety by the operator who attends to the moulds, and there is a contrivance by which, if any stone or other obstruction impedes the working, the parts are thrown out of gear, and the impediment can at once be detected and removed. The machine on the ground was worked by two horses, but it is equally adapted for steam power. The proprietors intend to exhibit this invention at the Ontario Provincial Fair.

A small steam engine and screw, constructed for a miniature propeller, also attracted considerable notice. It was made by Mr. Gilbert for the Harbour Commissioner. The entire weight of the engine and boiler is 29 cwt., the length of the boat is 36 feet, and it draws but 3 feet of water. The remaining implements consisted of the usual array exhibited on such occasions.

The display of grain, roots and dairy products occupied a comparatively small shed, and was in no way remarkable.

The Industrial Department, for which a temporary wooden building had been erected, was comparatively small in extent, and the articles, for the most part, were contributed by Montreal exhibitors. The utmost was made of the limited space, and the general arrangements, under the direction of

Mr. Pell, were excellent; but there was not sufficient light for an adequate display. On entering, the building the visitor was first attracted by the tastefully arranged stand of Messrs. Winning, Hill & Ware, who are celebrated for their cordials, liqueurs, syrups, and other articles of a like nature. This firm carried off the gold medal at the Paris Exposition. There was a fine display of domestic and monumental marbles from the respective firms of Forsyth and Mavor; and, adjoining these, were interesting displays of ornamental slate in imitation of various marbles. The patentees, A. K. and W. I. Mills, prepare this "marbleized slate" from the best material quarried in Vermont, and by putting on the marbled surface within the Province, can offer the manufacture at a much lower price than it can be imported from the States. The material is admirably adapted for a variety of purposes, and its introduction into Ontario would be a great advantage. The proprietors exhibited ornamental fire places, and a number of other articles, in very elegant and effective styles. It is very cleanly and well adapted for many homely domestic uses, as well as for decorative objects.

A large proportion of the building was occupied by stoves, furnaces, and the like. There was a fine display of carriages, a great variety of sewing machines, and a fair assortment of household furniture; besides a miscellaneous collection of manufactured articles, altogether too numerous to particularise.

The Show was, on the whole, a good one, and attracted a large concourse of visitors. With the improved accommodation and arrangements which will, no doubt, be carried out before another year, the Council of Agriculture hope to establish an annual Exhibition, which will assuredly be of great service to the Province in stimulating progress in the various industrial arts.

The Western Fair.

The Western Fair, under the joint auspices of the East Middlesex and London Agricultural Societies, was held in the show-grounds of the latter city, on the 27th and two following days of September, and was altogether a success. The weather was fine, and the grounds were filled each day by a large gathering of visitors.

HORSES.

The number of entries in the horse class was unprecedented, and the stalls were crowded to excess. Many should never have been exhibited, but there were in nearly every section animals that deserved distinction. Of blood-horses there was only a small show; but the numbers and general excellence of those in the agricultural section were considerably above par, while the chief bulk of the show in this department was made up by the road and carriage horses. In the heavy draught class there were some fine imported specimens—one shown by Mr. Buckland, of Guelph, was deserving of special notice. He is a Suffolk Punch, named "Britton," 4 years old, a powerfully built animal, and had in England twice gained prizes at the Royal Society's shows. Thomas Evans also showed a fine imported draught horse, "Canaby," 5 years old. There were also good native bred specimens of the same breed.

Among the agricultural horses considerable difficulty was experienced by the variety and distinct character of the animals entered under this head. Some were too light, and should have been considered roadsters, and others were decidedly too heavy and fitted only for draught work. The first prize for aged horses in this class was awarded to G. Teasdale, of London, for a fine bay stallion, "Royal Oak," 5 years old; and the 2nd to Leonard Hunter, of Osbourne, for his horse "Young Coachman," that has been a successful competitor in previous years. The 3rd prize was gained by A. M. Leach, of Brooke.

In the 3-year-old section, the highest place was gained by James Jackson, of North Dorchester, for a well-known stallion "Hard Fortune." The 2nd prize in this section went to Thomas Hodgins, of Biddalph, for a good bay named "Rob Roy."

The 2-year-old section contained one of the most promising animals on the ground, a bright bay, which deservedly took the first prize. He is the property of Daniel Flood, of London, was sired by "Anglo-American," and is a remarkably fine animal.

A few good yearlings were shown in the same section. "Captain Wallace," a horse of some celebrity, owned by Mr. J. Mason, of Clinton, was exhibited, but failed to get a prize. A beautiful black French Canadian stallion was shewn by Lachlan Wier, of St. Thomas, and was entitled to an extra prize. Among a number of good matched horses, a pair of superb greys, owned by J. Rutledge, of London, gained a first prize, and a promising pair of bays the second. In road and carriage horses Mr. Buckland shewed an imported animal of much merit. This section was very numerously filled, as was also that of horses for general purposes.

CATTLE.

The Durham class was well filled, there being 123 entries. In the two-year old section, Mr. McLeish gained the first prize for a roan bull, and Major Greig the second for his red and white bull, Harold—a decision which, in our opinion, should have been reversed. The yearling bulls were also good, and a very promising animal, shown by J. S. Smith, and bred, we believe, by Messrs. White & Kirby, took the first honours. Col. Taylor carrying off the second for Proud Duke, bred by J. O. Sheldon, of Geneva. In the yearlings, J. McGogan, of Strathroy, gained the first prize and diploma for the best bull on the ground. There were some excellent aged cows; the honours in this section went to J. S. Thomson, of Whitby, for Duchess 8th, who gained the first place. His yearling heifers, Christabel and Sylvia, attracted much attention, and won the highest honours in their classes. Major Greig's 6th Duchess of Oakland obtained the first prize in her class, two year old heifers; while in three year cows Bride of Greenwood was placed third, being beaten by Thomson's Queen of the May for first place, and Colonel Taylor's Elgitha for second. For Duchess 6th, of Oaklands, Major Greig gave $1,500 at the McMillan sale in Xenia, Ohio. Bride of Greenwood was also bought on the same occasion. Several of the others were from Mr. Cochrane's stock. The other breeds of cattle did not come up in numbers or excellence to the Shorthorns; but the Devons were, on the whole, a good class, and some of the animals shown were perhaps the best of that breed in the Province. There were a considerable number of grades, some of them crosses with Shorthorns, of superior excellence. There was also a fair show of fat cattle and working oxen.

SHEEP AND SWINE.

In addition to the live stock already noticed, the London fair had a good display in other classes of animals. The show of pigs and sheep, however, was seen to some disadvantage from the disproportion between the accommodation which had been provided for a Provincial Exhibition, and the diminished, though respectable, number of occupants in this local fair. Barring the drawback of long rows of empty pens, there was altogether a fine collection of Leicester and Cotswold sheep, and a few of other breeds. Among the pigs were a large preponderance of improved Berkshires, with some good Suffolks. Mr. Roach, of Hamilton, was among the most meritorious exhibitors, and had on view, besides a large number of animals bred by himself from imported stock, four recent importations of great value, consisting of an improved Berkshire boar, 13 months old, a Suffolk boar and two young Suffolk sows. Mr. John Corrie also exhibited some remarkably good animals, and among them a beautiful imported Berkshire hog.

POULTRY.

Of the poultry one expects in London a superior show, for the city and neighbourhood claim some of the most successful breeders of this class of stock. In the present exhibition there were a large number of entries, but a very considerable proportion failed to show, and the display, though a fine one, was in consequence much crippled. The season of the year is also somewhat unfavourable, and many good birds were in poor feather, and not at all in show condition. Notwithstanding these disadvantages, there was a fine display of nearly every variety of fowl. Among Mr. Lamb's best pens were buff and white Cochins, and a beautiful pair of silver pheasants. Mr. Peters showed some fine Dorkings, besides other excellent birds. Mr. Bogue's silver Polands were magnificent, as were also his silver pencilled Hamburghs. Mr. Fearman, of Hamilton, showed some superior dark Brahmas. Mr. Plummer and Mr. Lamb had each a fine collection of different varieties. Rouen and Aylesbury ducks were in force, and there was a good show of geese, both white and grey. A notable defect, which should by all means be remedied in future, was the absence of proper arrangements, a fault that seriously detracted from the effectiveness of the show.

IMPLEMENTS.

There was a fair display of the usual varieties of farm implements, contributed for the most part by well known exhibitors. Among the novelties deserving notice was a strongly built and effective stump machine, manufactured by Mr. John Plummer, of London, which seemed well calculated for its work. There was also a convenient construction of waggon, exhibited by Parker & Bateman, Strathroy, for the purpose of unloading by tilting over the box. This movement is effected when desired by the horses stepping forward. The same firm showed a simple and effective gate hinge, which allows of adjustment for snow, &c. Anderson & Johnson showed a meritorious invention styled a "lodged grain and pea harvester," which consists of a number of strong iron teeth that can be attached to any reaping machine so as to project beyond the ordinary guards.

HORTICULTURAL PRODUCTS.

This department of the exhibition was well filled, and the spacious shed appropriated to it presented a most attractive appearance. The display of fruit, especially apples, was unusually good, with a large competition, both in the general collections and varieties. For the best collection the first prize was given to one containing the following sorts :—Maiden's Blush, Cayuga Redstreak, English Russet, Northern Spy, Drap d'or, Spitzenberg, King of Tompkins' county, Beauty of Kent, Jonathan, Baldwin, Winesap, Dominie, Fall Pippin, Fall Orange, Canada Red, Golden russet, R. I. Greening, Kentish Fill-basket, and Snow.

The first prize for the four best varieties of dessert apples was given for Snow, Russet, Robin Hood and Golden Russet. For the best cooking apples—R. I. Greening, Gravenstein, Fall Pippin and Twenty-ounce. For the best 12 dessert apples (single variety)—Gravenstein, the best 12 fall cooking—Cayuga Redstreak—a remarkably good specimen; the best 12 winter dessert—English golden Russet; and the best 12 winter cooking—Rhode Island Greening.

The show of pears was small. The prize for the best six varieties was awarded for White Doyenne, Seckel, Glout Morceau, Louise bonne de Jersey, Flemish Beauty and Duchesse d'Angoulcme. The prize for the best three varieties was adjudged to Louise bonne de Jersey, Duchesse d'Angouleme, and Bartlet. In the single varieties Flemish Beauty carried the palm for dessert fruit, and Beurre Clairgeau for winter.

There was but a small show of plums. Mr. Saunders took a first prize for a plate of Dennistone's Superb.

Peaches also were but slenderly represented, the most meritorious specimens being seedling fruit raised by F. F. McMullen, the Verger of St. Peter's.

There was a remarkably fine display of grapes, to which the Hon. J. Carling contributed a meritorious collection, a noble bunch of Muscat Hamburg being conspicuous among them. Mr. Carling also showed a fine collection of plants in flower, which, with a similar one furnished by Mr. F. Rowland, and another by James Goodall, from the grounds of the late Judge Wilson, contributed much to the adornment of the room. The general display of flowers was, for the season, a good one.

Among the vegetables, the most worthy of note were potatoes, which were exhibited in unusual quantities and excellence.

The arrangements in the horticultural hall were excellent, while in some other departments, more especially the live stock, they were very bad. Another defect which, amid so much to commend, calls for passing notice, was the absence of any names of owners or premium cards, till the exhibition was nearly over. Reporters and the public were kept equally in the dark in these interesting particulars. There are some advantages in withholding the exhibitors' names, but we think the disadvantages counterbalance them; and, at all events, arrangements should be made for an early completion of the judging and announcement of the awards

IMPORTATION OF THOROUGHBRED STOCK.—Mr. John Miller, of Pickering, has just imported from England and Scotland a valuable lot of thoroughbred stock, consisting of one Shorthorn bull and eleven cows and heifers of the same breed—all of first-class pedigrees, and several of them prize-winners in British show-yards. He has also imported a number of pure-bred Cotswold sheep and Berkshire pigs.

Crops in the States.

An Associated Press despatch, dated Washington, Sept. 16, states :—

The August report on the crops, from the Department of Agriculture, says that the corn is injured somewhat in some localities by the drought, the wet weather, heat, worms, and heavy frosts, but not sufficiently as yet to threaten a material reduction of the product heretofore anticipated. The States showing a condition below the average are New Hampshire, Massachusetts, Rhode Island, Connecticut, Delaware, Maryland, Mississippi, Kansas, Nebraska, California and Oregon. There is considerable damage done to the cotton crop from rust, worms and unfavourable August weather, but the general prospect is not discouraging. There is little in figures to indicate a decreased yield of cotton, and favourable weather henceforth must insure considerable increase. Returns upon the wheat product pertain chiefly to the condition of the crops when harvested. The grain has not been threshed out to any considerable extent, so the October returns must be had before the estimate of the aggregate of wheat productions of the year can be made. The quality of the grain threshed is generally excellent, in many cases compensating for the deficient quantity. The rice and barley crops were generally harvested in good condition, with slight local drawbacks. There is an apparent diminution in the rye crop and also barley. Tennessee, Michigan, North Carolina, West Virginia, and Wisconsin are the only States in which the report of the prospect of buckwheat is above or up to the average. The middle or Western States indicate a decline of 5 to 10 per cent.; New England 15 to 20 per cent. The drought in many sections has materially injured the potato crop. In most of the States the quantity of the hay crop is above the average. Sorghum seems to have been entirely neglected east of Pennsylvania. The crop in most of the western States is reported in a fair condition. Louisiana and Florida report a sugar crop five to ten per cent. above the average. Texas, Mississippi, Alabama and Georgia report ten per cent below the average. California is the only State that reports an increased average in hops. The tobacco crop is reported 14 per cent. below the average in Connecticut; seven below in Massachusetts; 10 in Maryland; 17 in Mississippi; four in Texas; and two above the average in New York; five in Pennsylvania; four in Virginia; 14 in North Carolina; 10 in South Carolina; 13 in Georgia; 10 in Arkansas; 9 in Tennessee; 10 in Kentucky, and three in Ohio. There is an average in Missouri, Illinois and Michigan. There is much complaint of apples falling during the last two months and of retarded growth, caused by the dry weather. A fair product is promised in the eastern and middle States generally; and in Virginia, North Carolina, South Carolina, Tennessee and Kentucky, six-tenths of the average crops in the western States. The small decline in wool is favourable. The size and weight of the stock of hogs generally compare favourably with that of former years, except in several of the southern States and Illinois, Indiana, New Hampshire, Massachusetts, Connecticut and Oregon, which indicate depreciation in this regard.

This year will be remarkable in France for a great advance in the employment of agricultural machinery.

The International Agricultural Exhibition, announced to take place in Paris next year, has been brought to a stand still; and it would not be surprising if it was deferred, apart from the return of peace, till 1872.

EARLY ROSE POTATO.—This has proved to be the best second early potato this season, of good size, productive, and cooking dry and mealy. We commend it for trial.

The Quebec Board of Agriculture are about to compile and publish a Canadian Herd Book for Ayrshire Cattle, on a plan similar to the Shorthorn Herd Book issued by the Ontario Board of Agriculture.

The whole of the breeding stud of Colonel Townley, and the yearlings of Mr. Vaughan, were sold by auction by Messrs. Tattersall, at Fairfield. The sale was very slow, and many of the yearlings offered were withdrawn. There was only one case in which especial interest was shown, and that was in the competition between Mr. Hartington, of Limerick, Mr. Holmes, of Beverly, and Mr. Blenkiron, for possession of Breadalbane, own brother to Blair Athol, which eventually ended in favour of the last-named gentleman for £1,650.

A great breadth of barley has been raised this season in the county of Ontario, and the dealers expect large quantities will be brought to market. The Whitby *Gazette* says a great deal of barley has been carried over from last season, and advises all who are thus situated not to mix last year's crops with those of the present, as by doing so it will render the whole comparatively valueless. New barley malts more quickly than old, so that maltsters will not buy grain of different crops mixed together, as they cannot use them. Most of the barley crop is used for brewing purposes, and farmers will do well to recollect this caution, as otherwise they will find a difficulty in selling.

The Guelph monthly fair on October 5, had a large supply of cattle, but buyers were few and timid. The decline in beef in the United States, and the absence of the usual number of buyers at the Provincial exhibition tended to dull competition. The *Mercury* says fat cattle brought, live weight, from 3c to 4c, and one good animal sold for 4½c, which was considered a very good figure. Average animals sold at from $30 to $38 per head. Mr. Samuel Bidgeway, of Eramosa, sold a very nice heifer for $38. Milch cows were not in demand, and the class of animals offered was of inferior quality. The price asked ranged anywhere from $25 to $40. Sheep were on the ground in very small numbers. One middling lot was offered at $4 per head, but the buyers would not give more than $3, which was refused. Working oxen were present in considerable numbers. There was but little demand for them. A very fair yoke of these cattle could be had for from $75 to $100.

Miscellaneous.

Novel Application of the Sewing Machine.

The old country farmer, from his moist climate, and the large amount of manure he uses, both artificial and ordinary farm-yard manure, has more straw than he knows what to do with, and he also has more crops than he can think of putting entirely under roofed buildings. Consequently, the stack yard is to be found on every farm, containing a greater or less number of stacks of grain, beans and peas, and of hay, although generally there is a considerable amount of hay stacked near to its place of growth. But all these stacks are thatched with straw, and thus rendered completely weatherproof. The stacks of wheat, beans and peas, are only thatched on the roof, but barley, to prevent staining, is often thatched down the sides as well. The thatching bill in a large farm varies from £15 to £35 sterling annually.

Good thatchers are scarce, and some use more straw than others. Mistakes in the work happen, and then great destruction of the grain follows, for besides that which is absolutely lost, the sample of the whole is injured, and consequently reduced in price. In order to meet these difficulties, some ingenious person adopted the plan of constructing a large sewing machine, with large needles, sufficiently strong to carry good-sized tarred yarn, and of length enough to reach through the required thickness of straw. These machines put in two or more rows of stitching along the middle of a belt of straw, and at one end also in some cases. The straw is laid on a frame or table, and supplied in a continuous belt to the machine. The needles work alternately, so that one of them goes through the piece of straw stitched up by the other. The straw thus stitched together is rolled up in large rolls, and applied to the roof of the rick. The lower roll is put on first, all round the lower part of the roof of the rick, until the circuit is complete. The second row overlaps the first, covers over the stitches, and keeps them dry, the loose ends of the straw always overlapping. The mats or belts of straw are fastened on in the usual way, by pegs or spars stuck into the body of the roof of the rick, and thus the operation is effectually and quickly completed without the necessity of any specially skilled labour. Fifteen hundred feet superficial waterproof thatch can thus be made by hand power per hour; no doubt, when carefully taken off, it will last for more than one season.

Henry Ward Beecher on Interest.

No blister draws sharper than the interest does Of all industries, none is comparable to that of interest. It works all day and night, in fair weather and foul. It has no sound in its footsteps, but travels fast. It gnaws at a man's substance with invisible teeth. It binds industry with its films, as a fly is bound in a spider's web. Debts roll a man over and over, binding him hand and foot, letting him hang upon the fatal mesh, until the long-legged interest devours him. There is but one thing on a farm like it, and that is, the Canada thistle, which swarms new plants every time you break its roots, whose blossoms are prolific, and every flower the father of a million seeds; every leaf is an awl and every branch a spear, and every plant like a platoon of bayonets, and a field of them like an armed host. The whole plant is a torment and a vegetable curse—and yet a farmer had better make his bed upon Canada thistles than attempt to lie at ease upon interest

Building Lime.

As it is often of considerable importance to those who may wish to use lime for any of the purposes for which it is available that they should be able to distinguish a good article from that which is of inferior quality, we shall describe briefly a few of the common tests by which good lime may be distinguished from that which is poor. Of two pieces of lime about the same size, the heavier will usually be the best. There are a few marked exceptions to this rule, but in general it will afford trustworthy indications.

Good lime is greasy and unctuous to the touch; poor lime is dry and gritty; when good lime slacks in water it falls quickly, causes the water to boil up furiously, and gives out a great quantity of heat. The slacking of poor lime is attended with but a slight boiling of the water, and a small increase of the heat; moreover, the quantity of water required to slack good lime will be nearly one half its bulk. Good lime, when slacked, will swell to twice its original bulk, and if exposed to water continually changed, the lime will all be taken up without leaving any residue. Poor lime, when slacked, will swell to two and a half times its original bulk, and there will always remain a gritty residue, no matter how much water may be run over it.—*Am. Engineer.*

NEW ARRANGEMENTS AND GREAT INDUCEMENTS.

Wishing to give more attention to the raising of bees and queens, I offer the following inducements till the close of the coming Provincial Fair:—

To any person sending $3, I will send my single-boarded hive with improved entrance, price $3, or an individual right, price $3, and my dollar book on bee culture, soon to be published; tickets will be sent for the book. For $5, both hive and right, or an Italian queen, and the book. For $10, or the highest bid above that during the next six weeks, a township right and the book. For $12, or highest bid above that, a township right, one hive, and the book. For $400, or highest bid above that, a right for the entire Province of Quebec, with the exception of two or three counties that are sold; this right is worth $2,500. For $200, or highest bid above that, I will sell a patent for a Self-oiling Buggy Hub, lately introduced; specimen carriage to be seen at Brooklin, Ont.; this patent is worth $2,000. Sale of townships not to interfere with sale of hives upon the above conditions.

J. H. THOMAS,
2-5-tf. *Brooklin, Ont.*

FOR SALE,

SIX high-bred, Young Short-Horn Bulls, one by imported Crown Prince of Athelstane (21,512), 5,467; the others by the Imported *Pure Book* Bull, "Knight of St. George," (26,544), 5,472.

DOMINION OF CANADA

V. R.

EMIGRATION

TO THE

PROVINCE OF ONTARIO.

To Capitalists,
Tenant Farmers,
Agricultural Labourers,
Mechanics,
DAY-LABOURERS,

And all Parties desirous of Improving their Circumstances by Emigrating to a New Country.

THE attention of intending Emigrants is invited to the great advantages presented by the Province of Ontario. Persons living on the interest of their money can easily get eight per cent. on first-class security.

Tenant Farmers with Limited Capital

Can buy and stock a Freehold Estate with the money needed to carry on a small farm in Britain. Good cleared land, with a dwelling and good barn and outhouses upon it, can be purchased in desirable localities at from £4 to £10 Stg. per acre. Farm hands can readily obtain work at good wages. Among the inducements offered to intending Emigrants, by the Government, is

A FREE GRANT OF LAND

(WITHOUT ANY CHARGE WHATEVER.)

Every Head of a family can obtain, on condition of settlement, a FREE GRANT of two hundred acres of land for himself, and one hundred acres additional for each member of his family, male or female, over eighteen years of age.

All Persons over 18 years of age can obtain a FREE GRANT OF 100 ACRES.

The Free Grants are protected by a Homestead Exemption Act, and are not liable to seizure for any debt incurred before the issue of the patent, or for twenty years after its issue. They are within easy access of the front settlements, and are supplied with regular postal communication.

Registers of the Labour Market

And of Improved Farms for sale, are kept at the Immigration Agencies in the Province, and arrangements are made for directing emigrants to those points where employment can be most readily obtained. Several new lines of railway and other public works are in course of construction, or about being commenced, which will afford employment to an almost unlimited number of labourers.

Persons desiring fuller information concerning the Province of Ontario, are invited to apply personally, or by letter, to the Canadian Government Emigration Agents in Europe, viz.: Wm. Dixon, 11 Adam Street, Adelphi, London, W. C.; J. G. Moylan, Dublin; Charles Foy, Belfast; David Shaw, Glasgow; and E. Simays, Continental Agent at Antwerp.

Also to the Emigration Agents in Canada, viz:

John A. Donaldson, Toronto; R. H. Rae, Hamilton; Wm. J. Wills, Ottawa; Jas. Macpherson, Kingston; L. Stafford, Quebec; J. J. Daley, Montreal; E. Clay, Halifax, Nova Scotia; Robert Shives, St. John, and J. G. G. Layton, Miramichi, New Brunswick, from whom pamphlets issued under the authority of the Government of Ontario, containing full particulars in relation to the character and resources of, and the cost of living, wages, &c., in the Province, can be obtained.

JOHN CARLING,
Commissioner of Agriculture and Public Works for the Province of Ontario.

Department of Immigration,
Toronto, October, 1869. v2-2-12t.

Markets.

Toronto Markets.

"CANADA FARMER" Office, Oct. 14th, 1870.

FLOUR AND MEAL.

There is nothing of special interest to note in the breadstuffs market. The continuance of the continental war has but slightly affected prices either at Mark Lane, or in the United States, though if anything there is a slight upward tendency. The following are the Toronto rates:

Flour—Superfine, $5.15; Extra, $5.20; Fancy, $5.25 to $5.50.
Oatmeal—$4.40 to $4.50.
Cornmeal—$4.00.
Bran—$11.00 to $13.

GRAIN.

The demand for wheat is chiefly for local milling purposes. Barley is coming in pretty plentifully, but some farmers are still holding back for a rise. Oats are plentiful and prices remain steady.

Wheat—Sonies, $1.15 to $1.25; Treadwell, $1.10 to $1.12; Spring, $1 to $1.10; Midge Proof, $1.00 to $1.05.
Barley—Bright, 70c. to 75c.; inferior, 60c. to 65c.
Oats—37c. to 38c.
Peas—70c.
Rye—70c.

HAY AND STRAW.

Hay continues in good supply, and selling at $8.00 to $12.00.
Straw is scarce, and has sold as high as $10. From $6.00 to $8.00 may be considered the present price.

PROVISIONS.

Live Hogs—$6.00 to $6.50
Pork—Mess, $27.
Hams—13½c. to 17½c. wholesale.
Cheese—New, 12½c. to 13c.
Butter—17c. and upwards.
Eggs—12½c to 14c. per dozen.
Salt—Goderich, $1.65; American, $1.75; Liverpool, coarse, 75c. to 80c.; fine, $1.00 to $1.20.

CATTLE MARKET.

There is a free supply; many farmers running short of pasture and not intending to put over their stock during winter, are sending in their beasts to market.

Beeves—$3 50 to $5.
Sheep—$3.00 to $5.00.
Lambs—$2.25 to $3 25.

HIDES AND SKINS.

Hides—green, 8c.; cured, 9c.
Calfskins—11c. to 12c.
Sheepskins—65c.
Wool—30c. to 31c.

Montreal Markets.

Flour—Extra, $5 00 to $5 05; Fancy, $5 70 to $5 75; Welland Canal Superfine, $5 25 to $5 30; Superfine No. 1 Canada Wheat, $5 30 to $5 90; No. 1 Western wheat, $5 25 to $5 30; No. 2 Western wheat, $4 90 to $4 95; Bag Flour, $2.40 to $2 60.
Wheat—Canada fall, $1 15 to $1 16; western, $1 13 to $1 25 in bond.
Oats—Per 32 lbs., 40c to 42½c.
Barley—Per 48 lbs., 65c to 75c.
Butter—Dairy, 20c to 21c; store packed, 17c to 25c.
Ashes—Pots, $6 25 to $6 30; Pearls, $6 85 to $6 90.
Pork—Mess, $26 50.

Provincial Markets.

LONDON, Oct. 11.—Spring wheat, $1.20 to $1.29. Red Fall do, $1 to $1.09; White do, $1 to $1.20; Barley, 50c to 54c. Peas, 60c to 65c. Oats, 31c to 32c. Corn, 55c to 65c. Rye, 55c to 65c. Fleece wool, 28c to 31c.

HAMILTON, Oct. 11.—Delhi wheat, $1 20 to $1 22. Treadwell do., $1 05 to $1 06. red and amber, $1 05 to $1 06. Barley, prime, 70c to 78c; do., poor, 50c. to 55c. Oats, 34c to 36c. Peas, 55c to 60c. American fleece, 37c to 38c. Canada fleece, 30c to 31c.

OTTAWA, Oct. 11.—Flour—Extra, $7.25. Double, $6.25 to $7. No 1, $6.25. Oatmeal, $5 to $5 25. Cornmeal, $3.75 to $4. Oats, 50c to 52c. Peas, 60c to 70c. Wheat, $1.15 to $1.20. Pork, mess, $27. Beef, $5. Dressed hogs, $9 to $10.

GUELPH, Oct. 11.—Fall wheat, per bushel, $1.00 to $1.02. Spring, $1.05 to $1.15. Oats, 32c to 36c. Peas, 56c to 63c. Barley, 55c to 70c. Wool, 31c to 32c. Hides, per cwt, $5.50 to $6.50. Beef, $7 to $8. Pork, $7 to $8.50. Eggs, 15c to 17c. Butter, 15c to 19c. Pelts, 40c to 70c. Lambskins, 50c to 75c.

OWEN SOUND, Oct. 12.—Fall wheat, $1.; Spring do., 98c to $1 01. Barley, 50c to 60c. Oats, 29c. Peas, 50c to 54c. Butter, 15c to 17c. Eggs, 10c to 12c. Hay, $6 50 to $7.

THE CANADA FARMER is printed and published on the 15th of every month, by the GLOBE PRINTING COMPANY, at their Printing House, 26 and 28 King Street East, Toronto, Ontario, where all communications for the paper must be addressed.

Subscription Price, $1 per annum (POSTAGE FREE) payable in advance.

THE CANADA FARMER presents a first-class medium for agricultural advertisements. Terms of advertising, 20 cents per line space. Twelve lines' space equals one inch. No advertisements taken for less than ten lines' space.

Communications on Agricultural subjects are invited, addressed to "*The Editor of the Canada Farmer*," and all orders for the paper are to be sent to

GEORGE BROWN,
Managing Director.

THE CANADA FARMER

VOL. II. No. 11 | TORONTO, CANADA, NOVEMBER 15, 1870. | NEW SERIES.

The Field.

Early Winter Work.

By the beginning of December the farmer, if he is thrifty and industrious, will have completed most of his work, and gathered in all his crops safely under cover. Most that now remains to be done is the thrashing, cleaning, and marketing of his grain crops. There is an evident tendency on the part of many farmers to somewhat neglect the matter of properly cleaning their grain before taking it to market. So much has this been the case this fall that our barley, which usually ranks No. 1 and commands the top price from United States maltsters and brewers, has been brought to market in such a dirty state, and so full of foul seeds and failings, that the bulk of it has only ranked No. 2, and dealers on the other side will scarcely buy the cargoes sent over, unless at a considerable reduction below the price of western barley. This might easily be avoided by a more free use of the fanning mill, an implement that does not seem to be as much used and appreciated as it should be. A bushel or two of tailings or chaff left in a waggon load of grain, can, it is true, be passed off, but the entire sample will be rated at a price that will reduce the value of the whole much more than the loss incurred by leaving out the tailings would amount to. So far there is nothing to complain of in regard to prices, which are comparatively higher than last year, with a larger crop to sell; and really first-class samples are eagerly purchased at an advance on average values, while unclean and poor samples are neglected or can only be sold at a reduction.

IMPLEMENTS.—Now that the field work is over, every implement that has been in use should be brought in, cleaned, dried, and oiled or painted, and put away safely under cover, where no rain or snow can reach it. Let there be a place for everything and everything in its place before winter sets in. Every farmer should have a building set apart specially for the purpose of storing away his implements of husbandry when not in use. All that are broken or damaged should now be thoroughly repaired or replaced, and this done, there will be no time lost in spring when the season for work again comes on.

FENCING.—With the return of cold weather and a frost-bound soil, the farmer should endeavour to cut and split such rail timber as may be required for renewing or repairing of fences. This work is more easily done when there is little or no snow in the woods, than after the heavy winter storms come on. With the woods nearly clear of snow, it is much easier to see where to lay out the rails and pile them in places that are easily accessible when the sleighing becomes good enough to draw them to the clearings. Pathways for the team to get at them should be cleared out, while the nature of the ground can be seen, so that holes and bogs can be avoided. So also with the supply of firewood for next season, which may, however, be cut later, though usually some portion of each tree can be made into rail-cuts, while others may be cut into cord-wood. By a proper method of arranging this matter much valuable timber may be saved to a better use than burning, and much time and trouble saved to those who have to do the work of hauling out the rails and firewood to the yard and fields. If the work of looking over and repairing standing fences that do not require re-laying has not been done, no time should now be lost in attending to the matter.

STOCK.—All the animals on the farm should now be under shelter, and no longer allowed to roam over the fields even though they may still obtain a bit of frozen grass, which at best is scarcely equal to good clean straw. Those who have valuable stock will of course see to their being well housed and kept warm and comfortable as possible, with abundance of food and water. Animals intended to go to the butcher in spring or early summer should be put up to fatten before they lose their summer flesh. They need not be highly fed at first, but care should be taken to give them a sufficient supply to keep them in thrifty and improving condition, till the time comes for pushing them rapidly forward. Those who have saved their corn-stalks or sowed corn for fodder, will find it the best plan to begin by giving out this feed at the commencement, and if the stalks are cut and steamed along with some roots or crushed grain, they will need little or no hay so long as this fodder lasts. Pea straw that has been well saved and is perfectly free from damp or mouldiness, makes excellent food when cut and steamed, and has considerably more nutriment in it than the straw of cereal grain crops. Sheep will often thrive well through the winter on pea straw with the addition of some roots. Cows that are giving milk need extra feeding at this time, to enable them to keep up the supply and give any return in butter, for without good and rich food, such as the best of clover hay and a little coarse-ground pea or barley meal, the cream that comes from the milk will contain but little butter and be difficult to churn.

The store pigs must not be neglected, for upon their being kept thrifty and in a constantly growing state will depend the success of the farmer in turning out profitable pork. They should get warm quarters and plenty of food. Cut clover hay mixed in with steamed or boiled roots, ruta bagas especially, and given warm with a little pea meal added, is capital winter food for store pigs and breeding sows. Keep their sties dry and well littered with straw and sheltered from storms or snow drifts. Nothing can be more unsightly and liable to create disease among pigs than the filthy state in which too many farmers allow their sties to remain during cold weather.

SALTING DOWN PORK.—To have good pickled pork the meat must be from pigs not exceeding 150lbs. dressed. Cut out the hams, and cut the rest of the carcass up into medium-sized pieces of from 5lb. to 7lb. each. Rub each piece with fine salt, and set by for two or three days to draw out the blood.

UNIVERSITY OF TORONTO SEP 7 1954

Have a nice, but not very strong, well-boiled pickle, made from Goderich salt; lay the pieces in the tub or pickle barrel and pour enough of the brine on when quite cold, to cover the pork entirely. In about a month the pork will be fit to use, and may be kept for any length of time in the pickle, so long as it is fresh and good. If it begins to get the least bad taste, the brine must be re-boiled, or new pickle made, and the pork taken out and put in fresh tubs or barrels, and again covered with the brine.

Bacon and hams are best cured by first well rubbing in dry salt mixed with about one part in 400 of fine saltpetre, and afterwards covering with dry salt till they have become well salted, which generally takes three weeks, after which the meat is to be hung up in the kitchen to dry, or smoked, as soon as salted enough.

DITCHING AND DRAINING.—Much work of this kind can be done even after the ground is frozen or snow falls. It may be requisite to use the pickaxe to break the frozen crust, but that done, the soil underneath will be easily dug out. If the lines of the drains have been marked out, and the surface soil loosened by the plough, it will greatly facilitate the work. Tiles may be drawn on the land during sleighing, and everything got ready for an early commencement of laying the drains as soon as spring opens and the snow is gone, before the land is dry enough to be put under crop. The value of drainage to the soil is as yet little understood by our farmers, still there is always something being done towards the improvement of the soil, and good well-made under drains soon show profitable returns in the increase of the crops and the doubling of the value of the land.

MANURE.—Every effort should be made to increase the amount of manure made on the farm. Every dollar's worth of manure judiciously added to the soil gives a return of five dollars in the increased yield of succeeding crops for years afterwards. The manure heap is the farmer's savings bank, and pays cent. per cent. per annum for every dollar's worth of material and labour put into it. Everything in the way of vegetable matter, swamp muck, and scrapings of the roads and yard lanes that can be procured, should be hauled to the compost heap; and the droppings of the stock that are confined to stables and byres are better added to the heap than lost among the litter of the straw yard, which should rather be made the absorbent of the liquids, and get decomposed in the course of time. Too much of the manure is wasted by being scattered about in the straw, where it can not become of nearly so much value as if carried to one side and properly manipulated in the compost heap.

Of Peruvian guano, the total export last year was over 500,000 tons, of which Belgium took 82,000; England, 196,000; and North America, 25,000 tons.

Beet Root Sugar.

NO. VI.

Having now gone fully into the reasons why it is the interest of the farmers of Canada to engage in the growth of beet root of the sugar varieties, in the place of mangel wurtzel, and as an assistant to the turnip crop, I will proceed to the best-known methods of manufacturing the sugar, at the same time offering such suggestions for the purpose of simplifying the processes, as a considerable practice in general manufacturing, and good knowledge of mechanics and the practical chemistry of the industrial arts, may suggest. I make this as broad as possible, my object being to put on record the several methods of proceeding, so as to prevent persons patenting any of the processes, and thus delaying the introduction of the manufacture of beet-root sugar into Canada.

WASHING THE ROOT

This is the first process. The washing must take place in a rolling cage, in a trough partly filled with water, the cage being slightly depressed at one end, partly open at both ends, and the lower segment of the circle—the full length of the cage—being immersed in the water; the trough turns by machinery, with hand, horse, or steam power, and the roots are thrown in at the upper end; they gradually work along the cage, as it turns in the water, and are discharged at the lower end in a clean state. A stream of water should enter at the lower end of the trough, and flow through it, and out at the upper end, thus carrying the dirty water off, and leaving the *clean* end of the cage constantly supplied with *clean water*, whereby the roots are rinsed as clean as water will make them, with the least expenditure of water. The trough should in large concerns be fitted with a rolling cloth or frame of wooden slats closely joined together, which receives most of the dirt and sand, and carries it away. The water (where it is scarce) should flow off into a long trough or ditch, and be made to traverse as great a distance as possible, during which time it will deposit the dirt and sand, and may be used again from the farthest end of the ditch, and thus a great economy of water may be secured.

GRINDING.

This is done in several ways. In small concerns, or where better cannot be had, a sheet iron grater, punched like a nutmeg-grater, but of course much coarser, and made to revolve, will cut the roots into pulp at a considerable rate, but it should never be used where better can be had.

The next cheapest rasp, and one perhaps as efficient as any, may be made of a cylindrical wooden roller, with turned iron axles and journals, all, of course, fastened in a proper frame, and of strength sufficient to do the work without chance of breakage. From end to end of the cylinder channels are cut, into which are inserted lengthwise saw blades, similar to the blades of the common bucksaw, but thicker; these are held in their places by double wedges in the grooves, or pins into the body of the wood, and project a little more than the depth of the teeth. As many as eight or ten of these saw-blades may be inserted at intervals round the cylinder—they, of course, project equally. The saw-blades are made movable; the teeth of one should be opposite the vacancies of the next; they can be taken out and sharpened as occasion requires. They are filed in the ordinary way. The blades, where wedged into the wood, should be covered with a good varnish, or be well painted to prevent rusting. This cylinder is made to revolve rapidly, and the roots are presented to it in any convenient manner, and are thus reduced to pulp, which is received below.

A similar cylinder may be made with thick steel blades, inserted in the same manner, and ground to a thick edge, which is sharpened as occasion may require, by the removal and grinding of the blades.

Another form of cylinder is made by a number of circular saws punched out of iron plates (teeth and all are punched at one motion); there is a central hole with a key slot. A number of these are put on a turned iron axle, with intermediate smooth plates of iron of a less size, so as to allow of the teeth being set broadways like a saw, and this, though an expensive, is a very efficient tool, particularly if the saws are made of steel of the best quality. All the saws and plates are held firm on the centre by a key, or by two keys, wedge-shaped, going from end to end, along a flat place made in the spindle.

Another plan is the insertion of a series of flat cutters, like plane irons, round the circumference of a wheel, and which are set so as to shave or scrape the roots when presented to them, endwise, into the thinnest possible shavings.

Any of these plans, well carried out, will produce a pulp which can be pressed at once. The roots are presented to the grater (let it be in what form it may) by either hand power or machinery. The grater or rasp should revolve with great rapidity, and the resulting pulp be like soft wet snow, the finer the better.

PRESSING.

The pulp, when ground, may be pressed in any of the following ways:—

1st. In cloth or linen bags, with a powerful screw press. In this case the bags or cloths have only a small quantity of the pulp put in each. Cloths are best; they are put in frames to be filled, and the ends of the cloths folded in. Each parcel of pulp thus made, which should not be more than two inches thick, is then put on a board, or iron plate, and gradually piled up one on the other, under the press, until the limit of the screw is reached; the pressure of the screw is then brought to bear evenly through the medium of a thick cap-piece, made by crossing strong two-inch oak plank, well screwed together. The pile of filled cloths stands in a tray under the screw to receive the juice, which is then carried off to the boilers.

A second method of pressing is similar to the above, but the press, instead of a screw, or series of screws, is made of the ordinary hydraulic press, and is, of course, more efficient, although very expensive.

Many other presses of this description will naturally suggest themselves to the mechanical mind, and will be used where necessity, or limited pecuniary means, prevent the use of more expensive methods.

DEFECATING THE JUICE.

This has been partly described in a former article, but as other processes are mentioned more at length, it is believed that a repetition will be beneficial, and sure to fix the matter in the mind of the reader.

When the juice is obtained from the press, it runs, as quickly as possible, into the boilers, being strained from all traces of root and pulp. Hydrate of lime (hereafter described) is added to a greater or less amount, according to the process to be used, and the liquor in the boiler is brought to from 165° to 168° of heat (Fahrenheit's scale). A thick scum then rises, and when it has risen sufficiently, the liquor is brought so nearly to a boil as not to break the head of scum, which is then removed, and the liquor, now clear, and out slightly coloured, is boiled until sufficiently evaporated, when it is ready for the

SUBSEQUENT PROCESSES.

These are several in number, according to the product required. For the farmer or small manufacturer, who has not the necessary skill for the refining process, it should be merely evaporated until it is of sufficient density not to ferment—just such as ordinary treacle or molasses—and this is then fit to barrel up and take off to the refinery, where it will bear a price in accordance with the care with which the roots have been grown, and the subsequent processes conducted. The most important point to guard against is burning or browning the liquor, and for this purpose, where it can be had, and the work is to be constructed on a manufacturing scale, a boiler specially constructed is required.

THE BOILER.

This should be made thus: The bottom should be conical, made double, of boiler iron, well stayed and strengthened so as to bear a heavy pressure of steam between the two skins, to do the best possible work. Steam is the only heat which should be used. There must be an inlet for the steam, and an outlet back into the steam boiler for the condensed water to flow back into the boiler. The iron part must be made by a boiler-maker, and be calculated to bear the full pressure of ordinary high pressure steam. The top, or upper portion of the boiler, may be made of wood; an ordinary hooped wooden curb will be sufficient, and is perhaps better than if made of iron. There must be what is called open steam attached to the boiler for special occasions; this is merely an iron pipe of an inch in diameter, connected with the steam boiler, and going to or near the lower part of the conical bottom. The steam is shut off and let on by a tap at the upper end of the wooden curb, and within reach of the workman's hand. There should be a pipe and tap fitted to the point of the conical bottom of the double part, to enable the operator to draw off sediment and to empty the boiler as required. There must be proper receivers under the boiler suitable to hold the several kinds of substances which may be withdrawn from it.

In addition to the open steam, the refiner or large manufacturer will require a special coil of pipes connected with the carbonic acid arrangement which will be described further on.

THE FARMER'S BOILER

This need not be an elaborate affair. The same boiler and evaporators which he uses for maple sugar would be quite sufficient to bring the sap down to the syrup which is proposed to form the staple of his manufacture. The Americans have many plans for boilers adapted to the purpose of reducing the juice of the sorghum and maple sap. These all do well, and are so extensively advertised in American publications that any person wanting such can obtain them ready-made without difficulty. In a former number of the CANADA FARMER, under the head of "Maple Sugar Making," this subject has been fully treated, and to those articles (Vol. 1, p. 39, also Vol. 4, p. 49,) the reader is referred. The great object to be attained is evaporation without colour or burning. Any means which will give this end is what is required.

In future numbers, the consideration of this important subject will be resumed. New works have lately been published, giving the latest discoveries of the continental manufacturers, and the information which those works contain will in due time be transferred to the columns of the CANADA FARMER.

No. VII.

PROFITS OF BEET ROOT GROWING.

On this subject there will doubtless be endless disputes and cavillings. Some of the best agriculturists in the Province maintain that turnips cannot be grown to profit *as a crop*, on account of the labour necessary, and that were it not for the destruction of weeds, the rotation and manure which that crop gives, the farmer would be better without it.

Others, particularly our friends round Guelph, rely altogether on their turnip crop as the means of fattening cattle, and it thus becomes the *cash crop*, and takes the place of fall wheat, which is now a failure in that district. Now as the usual mode of reckoning of the farmers in the County of Wellington is, that besides the turnips required for stock sheep and growing stock through the winter, they can fatten one good beast (ox or cow) for each acre of turnips grown, and as no man need expect to make more than from 30 to 35 dollars on the animal over and above the original cost (or worth of it), when put in stall, we may safely reckon the produce of an acre of the best turnips, cost what it may to grow, to be from $30 to $35, and that it can never produce more than $40 per acre gross,—out of which the cost of labour in growing and attendance on the cattle has to be deducted.

An acre of beets will cost no more to produce than an acre of turnips, the culture is the same, and also the manure and labour of sowing, hoeing, and harvesting the crop; the singling the beets may be a little more troublesome, but the advantages in not suffering from fly and the quick growth of the plant to smother weeds, far more than make up for that difference. Beets may be sown later and harvested sooner than turnips.

If ten tons of properly selected sugar beets can be raised on an acre, they are worth, delivered at the factory (say within three miles), four dollars per ton, or $40 per acre.

An acre of turnips as above produces from $30 to $40 per acre in cattle feeding.

An acre of fall wheat at 30 bushels per acre (and who would not be glad to be sure of that amount of crop), at $1 25 per bushel will produce $37 50.

An acre of barley, at 40 bushels per acre, and at 80 cents, will produce $32 00.

So that an acre of sugar beets, taking every contingency into account, is worth as much, to say the least, as an ordinary crop of any other farm produce in Canada. And in addition, if the farmer works the crop up into syrup, he may be certain of realizing fully as much more, or $80 per acre, exclusive of the wear and tear of sugar utensils, fuel, and labour. The refuse is supposed to be fed on the farm, and this worked into manure, and the value of it is not taken into account in either case.

Now it appears from the returns of the Patent Office at Washington ("Report of the Commissioners of Agriculture, 1868"), that the average production of a crop of cotton in the United States, is only equivalent to $56 25-100; the proceeds from an acre of tobacco to $60; and on both these crops the labour is immense, and, as they say, never ending.

These amounts are given in American currency at a time when fully one-third, if not more, must be deducted to bring them down to a gold standard, exclusive too of extra taxation, and these deductions leave an acre of sugar beets (at $40) quite equal to a crop of the great staples of the South, and if worked up by the farmer into concentrated syrup, of greater value than either.

But the advantages of the beet root crop, if raised as proposed and turned into syrup, must not be reckoned merely as an *assistant*, a supplementary crop; it can be pushed to any reasonable extent, and will really nearly if not quite double the cash proceeds of the farm by its returns, exclusive of the increase which will take place in the wheat and other grain crops from the manure afforded, and the improved tillage which is sure to result from increase of means and returns to the farmer on his average year's work. I reckon in the foregoing that the beet root crop will take as many hoeings as the turnip crop, but if managed with judgment there are strong reasons to hope that at least half the hoeing may be dispensed with.

To raise beets to the best advantage for sugar they must not be sown till well on to the middle of June, and they will be ready for the manufactory by the middle of September, and may be begun within the first week of that month; so that if the ground is properly prepared by early spring ploughing, and then by several harrowings and rollings, sufficient to keep down and kill the weeds, all the surface weeds having vegetated, the beets run ahead of those that survive, and from the short time they occupy the ground, the weeds have not time to go to seed. This is putting out of sight all the advantages of horse-hoeing, which are considered to be equal, whether in the turnip or beet crop.

A miss crop of turnips, from fly or drought, is a common occurrence; indeed, what with missed spaces and general troubles from this cause, turnips are always a precarious crop. Beets, if the seed is good, never miss; the seed does not perish either from wet or drought, and the root has been called "the root of scarcity," because when all else failed the beet succeeded; hence, whatever little extra trouble there is in the growth of it, when compared with turnips, it is amply made up by its unfailing certainty.

Then again, when it is once a plant of general growth, the cash return of forty dollars per acre can be had from the manufactory, long before the turnip crop can be realized on, so that the advantages of the beet over the turnip crop are too manifest to be disputed.

In all this, too, we must not forget the thorough manuring the ground gets from the leaves, which are always cut off in the fields, and ploughed under before winter, thus leaving the land in the best possible condition for either barley, or spring wheat, or oats.

These assertions are not speculative, or given without ample experience. In countries where beet sugar is grown, as the growth of beet increases, the number of cattle increases; the manure from the cattle is more than can be obtained in any ordinary farming, without the growth of that root, unless expensive artificial manures are used. So the grain crops increase, and the general fertility of the land is maintained and added to, whilst from the greater amount of hoed crops and partial fallowing, by harrowings, and cultivatings, the weeds diminish year after year, until the land becomes clean, instead of, as most of our Canadian farms now are, a mass of foul weeds only to be kept down by the entire loss of crop one year out of four by naked fallows, the result of which, however necessary since the failure of our wheat crop, has been poverty to the farmer, and a gradual yet surely increasing want of fertility in the farm.

The beet root cake is better food for cattle than the original root. It can be stored for future use, and it is the best possible food for milk cows, never flavouring or injuring the butter.

Those who live to see it, will marvel at the regeneration which the cultivation of the sugar beet will produce in Canadian farming. Come it must and will.

VECTIS.

A Backwoods Farm.

SOWING SPRING WHEAT.

Our sub-contractor failed in his contract to have the whole one hundred acres ready for spring wheat the following year, and although most of it was logged and partially burnt, yet the fencing was incomplete. Some disagreement among themselves caused this, and we only had about sixty acres of spring wheat sowed by the 20th May following. We sowed one bushel and one peck an acre, and it would have been plenty, but from the time it was sowed, after one heavy rain, we had not one shower until the first week in July, and about that time we had a few showers, just enough to save the wheat from destruction. I think we had one slight shower about the middle or end of June, but very little. The wheat that lay on or near the surface did not vegetate until this shower fell, and consequently that portion of the seed that had been better buried was up quite high. The effect of this was that at harvest, which was delayed until September 20th, we were obliged to cut the unripe wheat to save the dead ripe portion from being lost by shelling out. This was a great drawback, as part of each field would be quite ready to haul, whilst other portions would be quite green and damp. About this time also, as is usually the case, some heavy showers fell, and as the equinox approached, wet and cold weather set in, and our land being cradle-knolly, and the water lying in the hollows, the waggon wheels cut so deeply into the sod that it seemed utterly impossible to haul off the wheat to the barn. The load rolled and rocked about like a ship in a gale of wind, but ultimately all was secured and hauled home to the barn.

BOARD ROOFS.

Here more trouble arose. When we built the barn, we, of course, calculated to cover it with shingles, but no shingles could be obtained, and as lumber was plentiful from a neighbouring saw-mill, we concluded to use boards instead. This would have been sufficiently tight to save the crop, but the lumber was cut, as almost all lumber now is, with a large circular saw, and one not in the best of order, and consequently it was covered with circular marks made by the saw where some one or more of the teeth projected beyond its fellows. These marks or channels, as they ran in a circular direction early across the boards, afforded a perfect succession of little drains to convey the water from the centre to the outside of each board, and consequently under the batten that covered the joint between each two boards, and so directly through the track thus formed on to the wheat below. Our wheat was badly injured by this, and we had at once to procure shingles at any cost, pull off the boards, and lay the shingles as quickly as possible—and not until this was done was our crop safe.

We would have threshed it out, but it was too damp and wet from the unripe straw that was mixed with it. This trouble somewhat daunted us, but we were made of stuff too enduring to "lie down and die" under any difficulty that could be surmounted.

BUILDING THE BARN.

This was rather a serious undertaking, but it had to be done. We contracted with a framer to do the carpenter work—we only undertaking to get out the timber in the woods and haul it, find hands to raise the frame, and also haul the lumber wanted, and find nails. I mentioned a neighbouring sawmill as being conveniently situated. The preceding sleighing months had been taken advantage of to haul 1,000 logs to the mill to furnish the lumber requisite for the barn and stables. We got it sawn on shares, that is, every log that was cut and yielded say two hundred feet of lumber, was divided, and one hundred was for us, and one hundred for the mill owner. This worked well, and to our advantage. In clearing the land, we had to remove the timber at any rate, and we had more labour to spare during the winter than money. We thus got plenty of lumber on easy terms.

About the 1st of August, when our first

and greatest hurry was over, we had the timber all framed, and a raising day was appointed. I was very averse to "bees," but always made a comparative exception in favour of raisings. Here individual labour cannot get along; united strength is requisite to get the heavy timbers up, and as we had to go to our neighbours' raisings on the same principle, and from the same cause, we determined to have a "bee" ourselves. All was prepared and a day appointed, but before we could get the frame together we had to build a foundation, and set in the cedar posts. I would have had the posts at least six feet high, so that a cattle stable could have been formed underneath, but the framer exclaimed that such a barn was never seen, and that it must surely fall down broadside. It "might," he said, be well enough to build a barn on a stone foundation so high, or perhaps higher, or against a side hill, but to raise a barn so large as 100 feet long by 40 wide, and 20 feet high to the plates, built on level land, to be "gogged" up on cedar posts six feet above the earth, was just folly, as it would surely fall down. I was utterly unconvinced by these statements, but at length yielded, and the barn was raised on foundation posts, four feet above the earth—I would not give in to any lower—and this was pronounced very bad policy by many who were consulted. Many reasons were given, but I did not believe one in ten to be good, and I am only sorry I did not insist against all comers, and raise the barn on six feet posts, under the sills. The advantages are so many. We will suppose you do *not* make a cattle-shed or stable underneath the whole barn, as it would, of course, entail the necessity of the floors in the mows being strong enough to support the barn full of grain, but you can use the large cavity under the barn floors; and our barn had two floors. And when the team is delivering a load of wheat sheaves it is very much easier to pitch those sheaves off the load down six feet into the mow below the barn floor, than it would be to pitch them six feet above it; and your barn, moreover, is one-third larger with each mow six feet below the level, and you can load through the floor in a waggon backed in underneath so easily. Then the sills never rot, as the manure never accumulates against them. Rats and mice cannot so well do mischief, and when unloading hay with a horse fork you have an infinite advantage in pitching down hill. There is literally no disadvantage about it, with one exception, and that is the hauling up an inclined plane to reach the floor, and here again the difficulty is small, as I have seen several large byres at Messrs. Gooderham & Worts' cattle feeding establishment in Toronto, where all the hay is hauled from choice up an inclined plane, and into the immense building above the cattle, so as to avoid as much as possible all pitching upward. Here the waggons absolutely pass over the cattle stalls. And where people are feeding a thousand head of cattle, as is the case in the byres above mentioned, saving of labour of men at the slight cost of constructing the inclined plane, and an additional pull for the team when hauling in the grass and hay, is a great advantage.

Farmers do not readily alter their ancient course. As others about them do and have done, so they do and continue to do. But the progress of the world is forward, and every one's mind should be readily open to conviction and trial, and an attempt to adapt other people's increasing experience to their own wants and case, rather than condemn wholesale what persons more ingenious than themselves have used. If manufacturers were to plump themselves down as farmers usually do, and say certain things will not answer because they have not been in the habit of using them, they would soon be left far behind in the race of life.

RAISING THE BARN.

In the course of getting ready for raising, my mind was still firmly bent on dispensing with a bee. I had procured a large and strong rope, and made three or four heavy pulley blocks, the use of which I was thoroughly acquainted with. I determined to try and pull up the heavy bents and timber by mechanical force, in preference to human aid. But I found such an active opposition to my plan from the carpenter and others interested, who knew nothing about the use of such means, that I abandoned as useless the contending any more about it, and the bee was accordingly summoned, and an excellent attendance of smart young men was obtained. There were forty asked; thirty-five attended. The frame was unusually heavy and large, the barn being 100 by 40 feet. with 20 feet posts, and consequently the bents were very heavy.

The first thing done was to choose two captains, one for each side. This was soon done, and they proceeded to select each a man from the mass for his own side, turn and turn about. As each name was called, the owner ran to join his party, and when those not chosen were left, they naturally were made to feel the small value set on them. Finally, all were selected but one Dutch lad, and much fun and merriment was held over him, as each party insisted on having him. So they tossed up a cent, head to win, and he fell to my party by lot.

Never having been at a raising before, I was much pleased at the wonderful activity of the second generation of Canadians. All nations were represented—English, Irish, Scotch, French, Dutch, Germans, and Prussians—and it would be invidious to state which were the best or more active, when all were running about like cats on the building, driving in pins, where nothing but twelve inches of lumber was to stand on; standing on the plates when only balanced on the points of the tenons, vieing with each other in the determination of each side to outdo the other in feats of daring activity on the building, as also in those of heavy lifts and carrying the ends of large pieces of timber.

Our bee of about 35 hands raised the building entirely in two and a half hours, during which time had our stolid Englishmen, who have been accustomed to move as if a hundred pounds were tied to their feet, seen the "second growth" Canadians at their work, they would have fully appreciated the activity and power of the young natives. Young Canadians from the agricultural districts are, physically speaking, as fine a race of men as are to be found—tall, spare, active and wiry. They will make their mark hand to hand with any nation on the face of the globe.

All hands then adjourned to wash, and to supper, after which all sorts of curious games completed the evening's amusement. If I could remember the German, French and Prussian it would be amusing, but I cannot. During the raising a large gathering of young women had taken place, and all were determined to give the hater of bees (myself) some idea of how an evening, after work was done, should be spent. It was about twelve o'clock before the dancing and games broke up, and nothing stronger than tea and coffee was produced to drink; all passed off pleasantly enough. The great bane of bees is whisky—avoid that, and they no doubt are very serviceable to some people occasionally, but I never liked them as a rule, when it was possible to avoid having them.

YIELD OF THE CROP OF WHEAT.

I had almost forgotten to mention the entomological fact that this year the wheat ears were covered with thousands on thousands of the blue aphis. Some of the ears were entirely hidden. The insects nearly resembled lice. We were quite alarmed for our crop. Our outlay had been large—nearly sixty acres of wheat sowing—and if this failed, we were in a bad position. However, all was not lost, as after threshing we had about 16 bushels to the acre; and had we had an entire absence of these insects, I am convinced we should have harvested more than 32 bushels per acre. The sample was excellent, and we ultimately sold all for seed at about $1 per bushel. In those days wheat was 65 cents per bushel for milling purposes.

HARVESTING TURNIPS.

We had an excellent crop of purple-top Swede turnips this year, and as the early part of November found us with the turnips yet in the ground, as a matter of course, occasional frosts and some slight falls of snow made pulling them a very uncomfortable sort of work. We had a man

working for us who offered to contract for the lot by the job—to take up the turnips, cut off the greens, and cart to the barn—we agreeing to find the necessary tools. In accordance with this arrangement, we provided a sharp steel hoe or two, and a sort of prong grapnel, shaped like a pitchfork, but having the tines of the fork about three inches apart, and bent close to the ferule, at an angle of 90 degrees to the handle—or rather inside this, say something within a right angle. With this machine he and his boy went to the field. He himself, with the sharp hoe, sheared off all the green close to the turnip smooth and clean, sometimes, indeed, rather too close. The boy followed, and by pecking the bent fork under each turnip, and pulling slightly backward, he pulled up the turnips with great rapidity. His father, however, beat him in cutting off the green tops.

When pecking out the turnips, the son first went lengthwise of the piece, and pecked up about one yard wide all through, leaving about three feet on one side untouched. On reaching the end he turned broadside, facing the piece left, and as each turnip was pulled up, he pitched it on towards the piece he had previously done. When he reached the end, he again picked up and jerked in towards the row thus formed, about three feet on the other side. This, when repeated, left the turnips in rows about nine feet from centre to centre. When they came to hauling, they drove the waggon down close to the row thus formed, and, with ordinary steel forks, loaded the waggon, generally with two turnips each time on the fork, and a most rapid and excellent plan it proved.

MAKING POTASH.

Our next care was to protect and collect the ashes out of which to manufacture potash.

After our great burn, of nearly 150 acres, there were of course vast quantities of ashes, exposed to the weather; and as soon as the heat of the burning brush had subsided all hands turned to, and raked the ashes into small conical heaps, usually containing about two bushels each.

This must be very carefully done, and also attended to before the ashes are cold, for unless they are raked before the heat is extinguished it is quite impossible to avoid drawing together some earthy and vegetable matter with them, which greatly injures the quality.

The weather looked unsettled; we therefore hurried our operations as much as possible, and all the ashes were raked together before any rain fell, and the heat of the unextinguished coals consumed the remains of any unburnt wood or charcoal.

We had at that time no place to store the ashes, and therefore had to construct an ash shanty, that is, to build a square log house, about 15 feet square, with a floor of logs to prevent the ashes being injured by the damp from the earth, and also a roof of a temporary kind, to prevent any very heavy rains from leaching the ashes from the top, thereby spoiling them. Our two teams, well attended to, soon hauled 700 bushels of ashes, and we were now ready to commence potash making.

We had previously received five potash kettles from Toronto; four were set in an arch, and one was used as a reservoir for lye. We built our leaches in the ordinary way, but took the precaution of so constructing the bottom that a complete filter of lime and straw caused the lye to be as free from impurities as possible, and as fine as wine, it was so perfectly clear. Unless this is done the quality of the potash will be inferior.

Having taken the precaution of ascertaining the fact that plenty of water was to be had on the spot selected, before locating our potash works, a pump was speedily made, and a well dug. Everything worked well, and we soon had two barrels of black salts, that is, crude uncalcined potash; and now came the melting off.

This is the climax of potash making. If the work up to this time has not been well done, the potash will not melt, and seconds or thirds in quality are the certain result. If, on the contrary, all has been carefully done, and all extraneous matter carefully kept out of the lye, nine times out of ten the melt will be easy. I have often seen people, who have neglected these points, fire away for hours to effect a melt, and actually honeycomb their kettle in their endeavours to accomplish this; and after all, when the potash was dipped out and cooled, it was only seconds or thirds. And all this extra trouble, and often the loss of a kettle, was caused by the presence of extraneous matter amongst the lye or ashes. Before we finally gave up potash making we had constructed a filter of lime through which all the lye was passed on its way to the kettle, and thus all difficulty of a good melt was avoided.

"Potash boiling," as it must be conducted nearly all night as well as day, is quite a jubilee time. In fine nights the brilliant fire attracts all the neighbours round, and songs and stories are plentiful and amusing. Many a good story I could tell that was related to me whilst boiling potash; but I must not trespass on the space devoted to agricultural matter by such narratives. I may perhaps be allowed to describe one or two adventures in which I was personally engaged.

COON HUNTING.

We had planted about four acres of corn, and the locality happened to be near the potash works. Raccoons were very plentiful and committed great ravages amongst our best roasting ears. Night after night we hunted them without dogs, fearing the mischief the dogs would do, but although we saw by the destruction in the morning that there must be several coons engaged, we could not catch one, they all seemed to make for one spot, and there we lost them. We procured good coon dogs and put them on the scent, but we still lost the game about one locality. One morning after the last unsuccessful hunt, I carefully examined the ground and all the old stubs about there, and was certain signs of "Coon" having ascended one large old elm tree, partly dead. I at once sent for some axes, and in half an hour the giant of the forest was laid low. It proved quite hollow near the butt, with a slight hollow all the way to the first large branches. I had a thorough-bred English bull-terrier dog, and I told him to jump on the stump and from thence into the hollow below, and of all the fusses you ever heard, that which issued from the stump's interior was the greatest. I pulled out the dog by the tail, and with him a fine large raccoon, and as he was splendid pluck and his blood was well up, next time I pulled him out with a coon in his jaws; he again jumped in, until we had eleven large and small raccoons. They fought hard, and my dog was considerably defaced in countenance, but no amount of punishment would daunt him. He never refused, if allowed again to go in, or gave bark until he had fastened on a raccoon, when we twitched him out by the ever whisking tail, coon and all. Of course a blow finished each of the poor wretches the moment they appeared in the dog's mouth. Our corn was safe from further molestation for that season.

BEAR HUNTING.

I recollect a desperate fright one of our men got about that time from a bear. Bruin thought corn good for him also. We had previously noticed some marks of a bear visiting the field. We were going our rounds one fine evening, and heard a rail fall off the fence. Of course we were instantly aware that some animal, tame or wild, had leaped into the corn field, and we at once suspected that we had arrived just in time to catch the bear in the act. I determined to go home for a rifle, and as we always carried a gun when prowling round the clearings at evening, anticipating some small game, I gave it to my man to hold, bidding him stay where he was and watch whilst I went for the rifle. He told me he had dropped a ball into one barrel, when loading the other with small shot before leaving the house; but as we had no more ammunition with us, I prefered getting another gun and some more powder and ball

My man was impatient in my absence, and consequently crept along the fence, until he judged he was about opposite the place where we heard the rail fall. Not a sound was heard, and he concluded to jump over the fence where the fallen rail lay and see; possibly we were both mistaken, and no animal whatever was there. He cocked both barrels, and carefully got on the fence. On the top he stopped and looked round, but could see nothing, save a large butt log of hemlock a few yards within the corn. He jumped fearlessly down, and the next moment up rose from behind the log, a monstrous bear, within ten feet of him. The bear rose on his hind legs with both fore paws hanging down, and for one moment looked stupidly at the man. He, poor fellow, who had only been a month in Canada, was terribly frightened, and yet the old poaching instinct prevailed. He was a capital shot, and instinctively raising the gun, he poured the contents of both barrels into the breast of the bear. In the smoke, not being able to see the effect of the shot, he threw down the gun and ran at a fearful pace towards the house. We met, and I was almost upset in endeavouring to stop him, and in fact did tear his jacket half off in holding on to him. His story was soon told, and when I had reassured him somewhat, we carefully and noiselessly returned to the seat of war, to find the largest bear I ever saw stone dead, with the contents of both barrels in his heart. This bear weighed nearly 600 lbs., and his hide was as large as a small cow's—a monstrous brute. But my man could never again be persuaded to go bear hunting.

Our potash paid well that season. The price was high and quality good, and before fall we boiled 22 barrels of No. 1, and two barrels of No. 2. Our gross return from this source alone was nearly $700. C.

Manure.—Lime.

All matters which, when applied to our soils, increase their fertility either by mechanical action, or by the supplying of certain elements of plant food, may fairly be considered under the head of "manures." Lime may, then, be termed a "calcareous manure," and is often of great benefit to our soils. By the discoveries of science, and the experience of practical men in the application of those discoveries, we have learned the great usefulness of lime as a manure.

Lime may be used in one of two states—*quick* or *slaked*. After limestones have been subjected for some time to the action of intense heat, they burn into a substance very caustic, and having an immense effect in causing the rapid decomposition of vegetable and animal bodies. This substance is *quick lime*. If water be applied to this quick lime, or if it be simply exposed to the air, it loses with more or less rapidity, according to which process be adopted, much of its caustic or burning power, and becomes "slaked" or "effete."

Now, the difference between quick and slaked lime is simply in rapidity of action upon substances with which they may be brought in contact—the former hastening decomposition much more rapidly than the latter. When the object of an application of this manure is to destroy and hasten the rotting of vegetable or animal matters, the quick lime has the best effect.

The action of lime is almost entirely mechanical. I say, almost entirely mechanical, for the fact that it does directly impart a certain element of food to plants is proved by chemical analyses, in that calcareous earth is found in the ashes of all vegetables, and in large quantities in those of wheat or clover. In 100 parts of wheat straw there are found 5 parts, and in wheat 3.35 parts of phosphate of lime. On the other hand, seeds planted in a pot of carbonate of lime will grow very feebly—in clear lime will die. Partly fill with garden mould and cover over with lime, and the plant will put down its roots through the lime to the mould, without throwing out branch rootlets until it arrive at the mould.

Great care must be used in the application of this manure, for it has different effects upon different soils and under different conditions. These conditions are so contrary, that while in many cases lime has been shown to have a most beneficial effect, in others its application has been fatal to all vegetable growth.

Lime has a strong affinity for acids. Its application to land, therefore, is beneficial in the following ways: It either renders harmless or converts into usefulness substances lodged in the soil, which, by their acidity, or, as named by farmers generally, "coldness," may be injurious to the growing crops, and thus prepares the land for the reception of seeds; it also greatly increases the rapidity of decomposition of putrescent manures, thus making them more easily available for the nourishment of vegetable life.

Lime has a great effect upon decayed and decaying vegetable matter, or, as we know it, "mould." There is no doubt that its application is of great benefit on "sour clays," for it corrects their acidity, and warms that sour mould which has been useless hitherto to plants, because it has required a quickening power to stimulate its further decomposition; also to land which has been at some time previous well dressed with "dung," without any addition of calcareous matter, by hastening decomposition; and rendering every particle of the rotting or putrescent manure available to the growing plant.

Now, in all arable lands, however much such may have been "run out," there still remains a large proportion of mould. Lime applied upon such land will quicken all that plant food which is lying dormant, and will greatly benefit the ensuing crop.

Let it be borne carefully in mind that lime has the effect of drawing out and placing within reach of the crop all the strength of the land, and it becomes evident that if its application be not followed by more manure, it will have the effect of rapidly exhausting the land.

It is useless and indeed injurious to lime too often, for if our land become surcharged with lime, having no putrescent matter to act upon, it will act too directly upon the crop itself, and greatly injure it.

Many farmers have, by advice, used lime on certain lands, and found that they have thus increased the yield of the ensuing crop. From this result they have deduced the truth that it is a grand manure, and have again and again applied it without further barnyard or green manure, to the utter exhaustion of the soil and the certain failure of future crops. Lime is a stimulant, correcting acidity and quickening the action of vegetable and animal manures, and like all stimulants, is good when used in moderation, but fatally exhaustive when taken in excess.

Low lands are immensely benefited by a free use of lime. Our low lands are generally rich with a deep black mould, but owing to their coldness, crops are not as heavy as the richness of the soil would lead us to hope. These soils contain in themselve all the component parts of the best soils, and are rich in decayed and decaying vegetable substances, but the manurial qualities in these lands are sluggish and inert, and will not freely give of their richness to the growing plant until stimulated by a free use of lime.

Heavy clays are often deficient in calcareous earths. In such lime is needed, and has often, too, the purely mechanical effect of making the soil more friable, and less subject to run together after rain.

Upon sandy land, which seldom contains much vegetable matter, lime has a contrary but good effect, attracting moisture from the atmosphere and giving more consistency to the sand, even as sand and lime become mortar.

"But if the soil consist of clay and sand," says Finlayson in his practical essays on agriculture, "containing animal or vegetable matter in a torpid state of decay, then lime would be preferable to dung. The state of the soil should therefore be minutely enquired into before lime is employed, and it should only be used to give effect to the inert substances with which it may be conjoined."

I cannot but think that a very free and liberal application of lime, ploughed in with our new lands when broken up, would increase their fertility wonderfully, for such lands are rich in vegetable matter, but are cold, inert in action, and acid. On such land I should use quick lime, as its effects are the more rapid, and it will destroy weeds and injurious plants.

The authority quoted above also says:—"There is this difference between the actions of lime and barnyard manure upon land: The former, being more stimulant and corrective, helps the farmer to an abundant crop at the expense of the land alone while the latter furnishes the land at once with fertilizing fluids, and will insure a good

crop on a place perfectly barren before and after the application of lime."

Lime is of great value to pasture land. So great an affinity has it for acids that it will greatly sweeten the herb. Indeed, if lime be spread upon a tuft of grass that has been refused by cattle, it will be found that they will soon detect the greater sweetness, and will eat it close down. When used for this purpose it must be slaked, for quick lime would be apt to burn the grass if used in any but very small quantities.

In the "General Report of Scotland" it is remarked that, "In the best cultivated counties, lime is now generally laid on finely pulverized land, while under a fallow or immediately after being sown with turnips. In the latter case the lime is uniformly mild—in the former quick lime, as pernicious (in a certain extent) to vegetation, may be beneficial in destroying weeds, and some experiments have been recorded, showing it to have a very powerful effect upon the fly. Sometimes mild lime is applied in the spring to land, and harrowed in with grass seeds, instead of being covered with a plough; and under this management a minute quantity has produced a striking and permanent improvement in some of the hill pastures of the south-eastern counties. Its effects are yet perspicuous, after the lapse of nearly half a century. In some places lime is spread on grass land a year or more before it is brought under the plough by which the pasture in the first instance, and the cultivated crops subsequently, are found to be greatly benefited. But in whatever manner this powerful stimulant is applied, the soil should never be afterwards exhausted by a succession of grain-bearing crops—a justly exploded practice which has reduced some naturally fertile tracts to a state of almost irredeemable sterility."

It is impossible to lay down any established rule for the regulation of the quantity of lime to be applied to land, for this must greatly vary according as the land is naturally calcareous or not, and also in proportion to the strength of the lime. It may suffice to say that in Great Britain the application, as made by her most eminent agriculturists, varies from thirty bushels to one hundred bushels per acre of slaked lime. Indeed, on some soils, as much as 400 bushels have been used per acre with great advantage.

Lime may be, and often is, used as a top-dressing on wheat, and the results of this proceeding have been various. I consider, however, that the lime will have a better effect, if applied to the land before it is shallow-ploughed the last time, or sown broadcast, and harrowed in with the wheat.

In conclusion, D. G. F. Macdonald says, in his excellent "Hints on Farming"—

"Lime, it would appear, may be always used with good effect under the following circumstances: 1. Directly upon mossy land, upon naked fallows, and in the spring, when preparing for turnips. 2. In composts in which the whole of the soluble salts of lime will have a tendency to be converted into gypsum by the action of the air; and consequently the benefits which result from a large application of the same, will be obtained by laying such composts upon the land. 3. It may be safely mixed at once with barnyard or other animal manures, though not in too large quantities. It may also prove a valuable admixture with guano, on which its action would ultimately be to fix, rather than expel, the ammonia. 4. Strewn sparingly over the young turnip plants, it is stated that it prevents the attack of the turnip-fly; and harrowed in when the ground is naked, if the quantity be considerable, slugs and wire-worms disappear rom its effects."

Many Canadian agriculturists have experimented with lime. Some have given us results in the CANADA FARMER. Let us have more experiences, and thus ventilate the subject, and give us the bounds within which we may steer, in order that we may improve the fertility of our lands, without exhausting our soil or ruining our crops.

C. E. W.

Ancaster.

Draining Wet Lands.

It is to be hoped that our farmers will be brought more and more each year to see for themselves that the proper drainage of their lands, wherever there is a field that retains water on its surface for any length of time, is one of the surest means of adding to the prosperity of the farmer.

We sometimes see a large meadow or field marred by a slash of wet soil through it, caused either by springs in that particular portion, or by the running down upon it and retention of water from springs higher up. This can often be easily remedied by making a good drain through this portion that will lead off the water to some lower level without the necessity of first percolating through and permeating with superabundant moisture, a large portion of the soil near the surface. Draining in this case ought to be resorted to, not so much for the sake of the land affected, as for the convenience of working the entire field, at all times when required, and so improving the entire farm.

There are sometimes to be found portions of land in the farm that are of good strong soil, but flat and cold, even when high up, retaining wet long after other portions of the field are ready for the seed. If such portions could be readily drained they would often prove as productive portions as any others in the field.

There are three modes of draining which may be employed, according to circumstances; namely, subsoiling, furrow-draining, and ditch or underdraining.

When a soil is underlaid by a compact impervious subsoil, all rainfall and melting snows will be retained near the surface until in process of time it can become evaporated. This compact subsoil acts like a water-tight floor. By subsoil ploughing we can work through and break up this undercrust, thus giving free egress downwards to the moisture that was previously retained near the surface, to the injury of the land and the plants growing on it. It will also help to prevent the injurious effects of drought in summer, as the breaking up of the hardpan enables the roots of the plants to draw up moisture from below, even when the surface is quite dry.

There is, however, a limit to the amount of usefulness of subsoiling. It has been ascertained in England that when a soil contains forty-three per cent. or more of alumina (clay) subsoil ploughing becomes useless, because, with so large a proportion of clay in the soil, it soon runs together again, and becomes as impervious as ever. In such a case, in the absence of underdraining, furrow draining must be resorted to. This is done by throwing the soil into high narrow ridges, ploughing back furrows, leaving the land so that surface water may readily run off into the furrows on either side before it can be absorbed into the soil. By leading these furrows into a ditch or underdrain, much of the surface water can be carried off the land, and the soil rendered much more workable and more amenable to the influence of the sun and the atmosphere.

Underdraining is, without doubt, the most certain and profitable method of improving all soils that are at all compact; but as few can afford the expense at the present high price of tiles and sufficiently skilled labour to accomplish the work satisfactorily, it is well to use other expedients, even if temporary, rather than continue to neglect the land.

Manure—Night Soil.

"The neglect of enlightened systems of agriculture precedes the decline and fall of empires. If the substances extracted from the land are not returned to it in the form of manure, the consequences must ultimately be disastrous to those guilty of such neglect. The sewers of ancient Rome have been highly spoken of, but at the same time it must be remembered that the *cloaca maxima* engulphed for centuries matters that would have greatly conduced to the prosperity of the Roman peasant, could he have obtained them. The Tiber became silted up, and when the exhausted fields of Italy failed to produce sufficient quantities of corn for the enormous population of Rome, and of other cities, recourse was had to Sardinia, Sicily and Africa, which also in the course of time became impoverished. The inundations of the Nile keep up the fertility of Egypt. The inhabitants of China and

Japan have contrived to maintain the fertility of their soil for thousands of years, mainly owing to the careful manner in which they collect and apply human excreta and other offal, which are justly regarded by them as valuable manures."

Chemical analysis shows us that all the elements which are necessary to the growth and life of plants are found in more or less abundance, not only in the various formations which are seen in a human body, but in great abundance in those substances which, after performing their necessary duties in strengthening and holding together the organization of man, are cast forth.

These substances expelled from the body are looked upon as base and loathsome, and are banished from all future use. Not only is thus wasted the most fertilizing agent that can be applied for the benefit of plant life, but the receptacles in which such are allowed to accumulate become noisome cesspools, from which emanate rank smells and poisoned air, and by which are bred disease and pestilence.

The quantity of valuable manure that the farmer may obtain from night-soil is not inconsiderable. The liquid and solid excrements of one man amount to 1½ pounds daily. This tells up to a large quantity in one year, and as this is the richest and strongest of manures, it has been computed that one man will, in a year, make sufficient, when mixed with other matter, to thoroughly enrich an acre of land, or to grow sufficient wheat for his own use.

Professor Liebig says in his Chemistry of Agriculture:—

"In respect to the quantity of nitrogen contained in excrements, 100 parts of the urine of a healthy man are equal to 1,300 parts of the fresh dung of a horse, and to 600 parts of that of a cow. Hence it is evident that it would be of much importance to agriculture if none of the human urine were lost. The powerful effect of urine as a manure is well known in Flanders, but human excrements are considered invaluable by the Chinese, who are the oldest agricultural people we know. Indeed, so much value is attached to the influence of human excrements by this people, that the laws of the State forbid that any of them should be thrown away, and reserves are placed in every house, in which they are collected with the greatest care. No other kind of manure is used for their cornfields."

The Chinese are, without doubt, the most admirable gardeners in the world. They use but very few horses in their agriculture, nearly all their work, owing to the density of the population, being done by hand. They place but little value on bestial manures, for they almost entirely enrich their cornfields with night soil. Of such value do they consider this latter, that the work of collecting and removing it employs an immense number of persons at all times and in all seasons.

The following tabular statements, the one of an analysis of human excrement by Berzelius, the other an analysis of guano by Voelcker, placed side by side, will give your readers some idea of the relative values of the two as manures:—

ANALYSIS OF HUMAN EXCREMENT, BY BERZELIUS.		ANALYSIS OF GUANO, BY VOELCKER.	
Carbonate of soda	3.5		
Muriate of soda	4.0		
Sulphate of soda	2.0		
Phosphate of magnesia	2.0		
Phosphate of lime	4.0

Muriate of ammonia	1.50	Urate " "	9.0
Earthy matter, lime and silica	1.06	Muriate " "	4.2
	1,000.00		100.0

How nearly then do guano and night soil resemble one another, each containing in great quantity those essential constituents of plant life which are most liable to be absent from our soils.

Of what glaring inconsistency are we then guilty! We throw away that which costs us nothing, and is yet so valuable, and at the same time incur an immense expense in the importation of guano from countries some thousands of miles distant.

The question now arises, how are we to collect and apply this valuable manure?

The best practical solution of this problem is furnished by the "dry earth system," which has repeatedly been explained and advocated in these columns. There is no mystery nor difficulty in carrying out the plan. The ordinary appliances of the farm are sufficient. All that is required is a store of finely sifted dry earth, to be kept under cover. A small supply of this material should be at hand in the privy. The receptacle for the evacuations should have a layer of the same at the bottom, and after each time of using, a pint or so of the dry earth should be thrown in to cover the fresh deposit. This will absorb the moisture, deodorize the ordure, and form a mass of the richest manure that can be obtained.

The same system may be carried out in the sick room, and will be found of great benefit to invalids, so perfect is the deodorizing power of the earth, and so simple is the working of the plan. For the general use of the house, commodes are now built, which combine simplicity of structure with a handsome finish, and are thus made to suit the closet in which the apparatus is permanently placed.

Whilst in England lately, I visited several earth closets, amongst which was one used by fourteen persons daily, and can bear my testimony to the perfect freedom from all disagreeable odours in each case. In every case the owners spoke in the highest terms of the satisfaction which had been afforded them by the adoption of "the earth closet system."

Ancaster.

Spring Wheat after Winter-killed Fall Wheat.

Some time since, while travelling in the West, I met with a most intelligent gentleman, from whom I had previously received many useful practical lessons and hints on various branches of manufacture and agriculture. Amongst others, he related his experience of the exhaustive effects of young winter wheat. He had found that, generally speaking, land on which winter wheat had been grown, and done well in the fall, but been badly winter-killed, failed to produce a good crop of spring wheat in the following spring; and his theory was that the wheat required a peculiar kind of nourishment when young, which it had found in the fall and duly appropriated to its use, in accordance with the ordinarily received opinion on the subject; that the young spring wheat grown on the same land the following spring required a precisely similar quantity and quality of nutriment, which, as a previous demand had been made in the fall, the land failed to supply; and hence the usual failure to grow spring wheat after winter-killed fall wheat, as such a course was equivalent to growing two crops in one year.

But, if barley had been sown in the spring instead of spring wheat, a bountiful crop has almost always followed. Many people can vouch for this fact, but very few, probably, thought out the cause, as my intelligent friend had done.

It certainly is a point worth consideration, and the opinion here given of the process and result appear reasonable, especially when we consider that an exactly similar consequence arises when wheat has been destroyed by the midge. In this latter case, the land has, we will suppose, produced a bountiful crop of Soules wheat, as has thousands of times been the case—say to the extent of thirty or forty bushels per acre. Just as the wheat is in flower, the midge in countless numbers strikes the whole, and the crop is not worth threshing, nor even the cost of harvesting. Now, all the constituents that ever had been taken from the ground to form this crop had been returned to it, as nothing has been removed; and we will say the straw is at once ploughed under, as I have often seen it done, by means of a chain and weight dragging down the standing crop into the furrow—

the chain and weight holding it down until the furrow slice covered it almost entirely under.

When green wheat is ploughed under in this manner, rapid decay takes place, and the whole of the previous wheat crop is returned to the soil again; and we will suppose a second crop of wheat sown the same year, thus virtually sowing wheat after wheat without cessation. We all know there would be no second crop of thirty or forty bushels per acre, even if no midge took it; we all feel quite sure of that, and the same train of reasoning as my friend carried out may explain the result, namely, the wheat was grown, and had abstracted the nutriment required to produce a crop. The midge destroyed it, and hence no more could be again grown until the balance was restored by a rotation of other crops or manure.

So it is with spring wheat following winter killed wheat. The balance of fertility has been disturbed, and a crop has been grown, a young one it is true, but still such a one as required for its support what the land was capable of finding, but which it could not find for both fall and spring wheat, even where fall wheat had been ploughed under.

C.

As only one item in the cost of a war, it is calculated that the farming classes in France have already lost £170,000,000.

M. Marix has taken, in France, a patent for the application of fluosilicic acid for the purifying of beetroot and other saccharine juices. The saccharine juices are first diluted with a sufficient quantity of water to ake away the viscosity of these fluids; sufficient fluosilicic acid is then added to precipitate all the potassium salts present; and next, chalk is added to saturate any excess of the acid. The fluid is then filtered in order to obtain a clear liquid, and this is afterwards treated in the usual manner.

SALTING WHEAT GROUND.—In answer to a question about applying salt on wheat ground, Prof. Whitney says:—"No reliance can be placed beforehand on the action of salt in any given case, or for any given crop, for the reason that its operation may depend upon any of a dozen different causes. If there is a deficiency of soda in the soil, salt may supply it; the decomposition of the salt may, by liberating one of its components, chlorine, hasten the germination of the seed, this element being believed to have this effect specifically, or the salt dissolving the soil may, as is known to be frequently the case, help the solution of insoluble phosphates. The ash of wheat kernels contains nearly 4 per cent. of soda, the ash of the straw nearly 2½ per cent., and that of the chaff more than 1¾ per cent. It is likely, therefore, that salt will prove beneficial to wheat, but this can only be found by actually applying it to a piece of ground and watching the result."

Stock Department.

Improving our Horses.

Notwithstanding all that has been done of late years by enterprising individuals towards inducing our farmers to use a heavier and better class of stallions as breeders, by importing Clydesdales and Suffolks at great expense, there are still too many light, weedy, worthless colts to be found growing up throughout the country. Too many of our farmers totally neglect or overlook the fact that there is a principle involved in breeding every kind of stock, and that is, that any deficiency of points on the side of the dam must be corrected in her offspring by using the sire that is full in those points, and has character and blood, acquired through a long descent, sufficient to stamp his good qualities upon the offspring of his get. To obtain really valuable horses for farm work, we must have and use only sires of a recognized breed or strains of blood, and generally of a heavier style than our farmers have hitherto been accustomed to, for as our mechanical appliances for performing farm operations improve, a heavier and faster class of horses is needed to enable them to be properly worked, the aim being to get the work done more rapidly under an improved system of labour. It was satisfactorily demonstrated as a fact at the recent trials of implements held at Utica, N. Y., that an increase in the rate of speed at which the machines were worked did not increase the amount of draught to the team to any extent. This was found to be especially the case with ploughs, it being shown that a fast walking team would do double more work in a day than a slow team, without increasing their labour, or the draught of the plough more than one tenth. This shows that, in order to double the amount of capacity for accomplishing work rapidly, we need only to add one tenth to the weight and muscular energy of our horses, while doubling their rate of walking.

For this purpose there is nothing better than the use of the Suffolk and Percheron as a graft upon our ordinary stock of farm horses. The Clydesdale is better adapted for drawing heavy loads at a moderate pace on good roads, than for farm work. It is slow in movement, costly to keep, and of uncertain temper, fit only to be entrusted in the hands of strong men. The Suffolk or Percheron is quite heavy and muscular enough, while, at the same time, they have a quick walking gait, easy docility of temper, and will work hard and keep up their condition on less feed than the Clydesdale. The Percheron stallion, wherever it has been introduced in America, has proved the best adapted to get stock suitable to the wants of our farmers of any breed known.

There is another matter in connection with breeding horses that is generally sadly neglected or overlooked, and that is the proper feeding and attending to the colts both before and after they are weaned. The mare is usually turned out to grass and left to herself without any attempt being made to increase the quantity and richness of her milk by feeding grain. She should have at least four quarts of oats per day, and so placed that her colt can get into the way of eating a share of it. In this way the colt will get accustomed to dry food before it is weaned, and if the grain is kept regularly supplied in increasing quantity, as the animal grows older, it will acquire a much greater amount of muscular development and power than if it had been left to grow up under the usual system of hard fare and many knocks amongst the cattle in the straw yard. It is a poor policy to let a young growing animal get stinted and stunted at the very outset, and lose all it has gained on summer pasturage, by neglect to properly feed and care for it during the autumn and winter. It is surely worth while for a farmer to double the value of the colts he may raise and bring them earlier to maturity, by a little extra expenditure of food and care upon them while young. Two quarts of oats a day to a colt for three years would come to 68½ bushels, worth say $27 00, while the colt's value would probably be at least $50 higher than if he had gone without the oats.

Early Maturity.

Prof. Miles, of the Michigan State Agricultural College, asserts, says the *National Live Stock Journal*, as one fact established by his recent carefully conducted experiments in feeding animals, that the importance of early maturity in animals raised for the production of meat is clearly shown in this series of experiments. In the manufacture of pork, the best return for the feed consumed, will undoubtedly be obtained by liberal feeding during the early stages of growth, and we cannot reasonably avoid the conclusion that the same rule is applicable to all animals raised for the purposes of the butcher. As animals are employed to convert the vegetable products of the farm into animal products of greater value, the greatest profit in fattening may reasonably be expected from liberal feeding during the period of growth, in which the organs of nutrition are capable of converting the largest amount of materials into animal tissues in a given time.—The results of experiments in pig feeding, show conclusively that animals when properly fed, give a much better return for the feed consumed, during the first few months of their lives, than they do after they reach maturity.

Foot and mouth disease is still seriously prevalent in Great Britain.

The Smithfield Club Cattle Show is to be held in London on the 5th to the 9th of December.

Weaning Colts.

We often, when travelling through the country in the fall, see colts with a rough, staring coat; eyes nearly closed, and a watery matter exuding therefrom, with a body shaped like a squash seed, which, but a few weeks before, while running with the mare, were possessed of a sleek, shining coat, eyes bright, and body as round as a barrel. Now the question arises, what is the cause of this? I answer, in nine cases out of ten, it is improper weaning. Nearly every colt in a farming community is allowed to run with its mother until about four or five months old, when, to suit the convenience of the owner, it is turned into some distant field out of sight, and if possible, out of hearing of its mother, there to run and whinney and worry, until it brings upon itself a fever, which weakens the constitution, closes the pores of its skin, and in brief, the whole organs of digestion become more or less diseased. All of this can be avoided by a little care in weaning.

My way of weaning is this—When my colt is four and a half months old, I put a strong leather halter upon him and place him in a stall, and put his mother in an adjoining stall, with a partition between, so arranged that they can see each other, and if possible get their heads together. The first day I let the colt nurse twice—the next day once. I feed the mare upon dry hay and dry feed, and about half milk her two or three times a day until dry. The colt I feed upon new-mown grass or fine clover hay, and give him a pint of oats twice per day, and in about two weeks I have my colt weaned and my mare dry, with my colt looking as well as ever. When he is one year old, he has as much growth and development of muscle, as one two years old weaned in the first described manner. When the mare becomes dry, colt and mare may be turned out together again in pasture.—*Cor. Rural New Yorker.*

Cross-breeds and Grades.

The distinction between cross-bred animals and grades is so seldom insisted upon that we are inclined to define the terms when used in connection. "Grades" among neat stock, sheep, and swine, are animals which have thoroughbred sires, with more or less, or altogether common blood on the side of the dam, while a cross-bred animal has both sire and dam thoroughbred, but of different breeds. Thus, if a common cow has a heifer calf by a Short-horn bull, the calf is a half-grade Short-horn, and her calf, by a bull of the same pure breed, would be a three-quarter grade Short-horn. The next grade would be seven-eigths, the next fifteen sixteenths, &c. Any pure-blood cow, crossed with a pure blood of another breed, produces a cross-breed, which, crossed with a full-blood or another cross-breed, would represent no gradation of blood, but be a cross-breed still, combining and exhibiting with considerable distinctness the characters of its different parent breeds, or the predominating ones.

In the case of grade animals, the common or native characteristics are often almost lost in the half or three-quarter grades, except perhaps some long-cultivated points, like the milking qualities of good, old, native cows, which are often intensified in their grade offspring. This is supposed to show the vital power of the breed, which has, as it were, accumulated through many generations. By the use, then, of thoroughbred sires, we are enabled to reproduce their valuable characteristics in their grade stock with great certainty. Inferior specimens always occur among herds of pure stock. These must be sold at low prices, or sent to the shambles. They may, however, if females, be used to great advantage often in breeding cross-breeds. As a rule, none but excellent animals should be used as sires of either thoroughbreds, grades or cross-breeds. —*American Agriculturist.*

The sale of thorough-bred stock at Bow Park on the 20th October, went off successfully. A great crowd of persons attended the sale, and all the animals on the catalogue were disposed of at good prices, with the exception of a few lots of sheep that were not reached when night approached.

Three valuable horses imported by Mr. Teasel, of Belleville, were lost on the *Atlas* in her recent voyage from England by sickness caused by bad weather. One animal was insured for £400 sterling, but from the reading of the policy it is doubtful if the loss can be recovered, notwithstanding all due care was used during the voyage by those who had charge.

Over 600 head of cattle were on the grounds of the Arkona cattle fair on the 12th inst. Three hundred had changed hands at prices ranging from thirty to forty dollars for steers; one hundred to one hundred and twenty dollars a yoke for oxen; and twenty-five to forty dollars for milch cows. Altogether, the fair was one of the best held in that section.

Considerable alarm has been excited in England by reports of the appearance of rinderpest near Berlin. The exigencies of the war, it is supposed, have caused some relaxation of the stringent regulations respecting the admission of cattle from Russia into Germany, and hence this fatal disease has once more passed from the Russian steppes, where it is mostly confined, into Western and Southern Europe.

J. H. Wallace gives the *Country Gentleman* some interesting facts as to the results of breeding from stallions at various ages. These show that some celebrated horses have been raised by stallions from 20 to 27 years old, and again that equally good ones have been raised by stallions of only two, three, or four years. He concludes that the question of age is not so important as that of condition.

Veterinary Department.

Chronic Nephritis.

Inflammation of the kidneys in the chronic form is more frequently met with than the acute disorder in the lower animals, and aged horses are frequently found affected with this disease, especially such as are exposed to sudden changes of temperature and other debilitating influences, and that have been often dosed with large quantities of medicines possessing diuretic properties. The symptoms resulting from chronic nephritis are a gradual loss of flesh, pain in the region of the loins, and impaired action of the hind extremities. The urine is also occasionally very high colored.

In treating this affection, the horse should be allowed perfect rest, and have a generous diet of easily digested food; also plenty of mucilaginous drinks. The loins may be rubbed every third or fourth day with mustard; and one drachm of tartar-emetic given every night. This medicine can be conveniently administered mixed with the food.

Enlargement or hypertrophy of the kidney also occurs, and cases have been met with where the kidney was enormously enlarged, and found to weigh upwards of fifty pounds. In cases of hypertrophy of the kidney very little can be done to afford relief.

Urinary Calculi.

A frequent cause of irritation in the urinary organs, either of the horse or ox, is calculi, which are found throughout the whole of the organs, and are classified according to their situation. When found in the kidneys, they are known as renal calculi; in the ureters, as uretral; whilst in the bladder, they are designated cystic or vesical.

In certain diseased conditions of the kidneys they are frequently found in great numbers. The general symptoms of urinary calculi, are a difficulty in urinating, and the urine presents a difference in its colour, sometimes being very light, in other cases very dark, and apparently mixed with blood. The patient occasionally shows colicky pains, by lying down and rolling, and gradually falls off in condition. When the calcareous deposits are situated within the bladder, they frequently attain considerable size, and cases are noticed where the calculus has weighed several ounces. Vesical calculi are also found to differ in their character; some specimens are very hard, whilst others are of a soft pasty nature. In all cases they are found to be composed largely of some of the combinations of lime, and particularly the carbonate. It has also been noticed that these concretions are oftenest met with in horses pasturing on limestone districts, or when the drinking water contains lime in large quantities. Cystic calculi can gener-

ally be readily detected. The urine is very high coloured and tinged with blood, and passed often. When the stone passes towards the neck of the bladder, it produces retention of urine, which is speedily followed by acuto pain, and the horse throws himself about, straining violently and looking towards his flanks. In other cases he walks with a stiff straddling action. When the above symptoms are presented, an examination should be made *per rectum*, which will tend to reveal the nature of the disease.

In the treatment of urinal calculi, the mineral acids have been found beneficial, as one drachm of hydrochloric acid daily, which must be largely diluted with water, and its use continued for some time.

Sweany.

A correspondent writes for information respecting the nature and treatment of "Sweany."

The injury of the muscles situated on the outer part of the shoulder is a very common occurrence, and is usually known among the farming community as "sweany." Professionally spreaking, it is generally designated "shoulder-slip." In young horses, the muscles are frequently injured from over-exertion or from going in an awkward manner when first put into harness, or from badly-fitting collars, causing an uneven bearing upon the shoulder. The process of nutrition is partially arrested, and the muscles waste, producing a hollow extending from the upper to the lower parts of the shoulder. In severe cases, the horse, when walking, has a peculiar rotatory motion of the limb, that is sometimes mistaken for dislocation of the shoulder joint. The outward motion is the result of the muscles on the inner part having no counterbalancing power. Cases of shoulder slip are usually treated successfully. The horse should be kept quiet, and the shoulder rubbed once a day with a mild stimulating liniment, and in some cases a sweating blister has a good effect. When the process of reproduction begins, moderate walking exercise is attended with benefit, as is also a run at pasture. Where the muscles are greatly atrophied, it usually takes two or three months before the animal is perfectly sound.

The term "sweany" is also applied to a slight wasting of the muscles, the result of injury to the lower part of the limb. In prolonged cases of foot lameness, as in navicular disease, the muscles become shrunk from the impaired action of the limb.

VESICLES ON THE UDDER.—A "Northern subscriber" wants advice respecting his cow, which he says is "affected with matter blotches, that break on being pressed in milking." Without more precise information we can only guess at the nature of the ailment, which is probably "cow pox." If so, no particular treatment will be required.

The Dairy.

Injuries and Obstructions in the Teats.

The teats of the cow are liable to various affections, which more less impede the flow of milk, or stop it altogether, and often form the basis of an inflamed state of the udder. One of the chief causes of these obstructions are small tumors about the size of a pea, which may be felt on compressing the teat between the finger and thumb, and can be often moved up and down the teat. Sometimes these entirely stop the flow of milk, and at others a small stream can be got by much pressure. These small substances are either what are called lacteal calculi (*milk stones*), or tumors attached to the lining of the teat. In these cases, a silver probe, or a knitting needle, must be passed up the teat, and the obstruction either broken down, or passed into the udder, where they often remain without inconvenience. It is not often possible to extract them from the end of the teat, nor should this be tried, as from the irritation caused, inflammation is frequently set up and the quarter is lost.

Strictures often exist in the passage of the teat, diminishing the flow of milk. In those cases a probe, or knitting-needle as large as the stricture will bear, and gradually increasing in size, should be frequently passed, so as to distend and keep the passage open.

Warts at the end of the teats are occasionally found, and are a great annoyance, not only obstructing the milk, but, from their soreness, causing the cow to become fidgety and uneasy while milked. In these cases the wart must be removed, either by the knife or by a ligature of fine silk tied around it; the latter is the preferable mode, as warts, when *sloughed off*, are not so liable to return as when excised with the knife.

Sore and chapped teats are best treated by the application of ointment of turpentine, (Venice turpentine, two ounces; hog's lard, four ounces; dissolved with a gentle heat and mixed,) or an ointment of Verdigris, (Verdigris in fine powder, one part; common turpentine, one part; hog's lard, twelve parts. Melt the two latter ingredients first, and then add the verdigris, stirring till cold). *Prairie Farmer.*

About Milking.

Five per cent., and perhaps ten, can be added to the amount of milk obtained from the cows of this country, if the following rules are inexorably followed :—

1. Never hurry cows, in driving to and from the pasture.

2. Milk as nearly at equal intervals as possible. Half-past five in the morning and six at night are good hours.

3. Be especially tender of the cow at milking times.

4. When seated, draw the milk as rapidly as possible, being certain always to get it all.

5. Never talk or think of anything beside what your are doing when milking.

6. Offer some caress and always a soothing word when you approach a cow and when you leave her. The better she loves you, the more free and complete will be her *abandon* as you sit at her side.

We append the not uncommon practice :—

1. Let some boy turn the cows away and get him who is fond of throwing stones and switching the hind ones every chance he gets.

2. Milk early in the morning and late at night, dividing the day into two portions, one of fifteen hours and the other nine.

3. Whack the cow over the back with the stool, or speak sharply to her if she does not "so," or "hoist."

4. Milk slowly and carelessly, and stop at the first slacking of the fluid.

5. Talk and laugh, and perhaps squirt milk at companion milkers, when seated at the cow.

6. Keep the animal in a tremble all the time you are milking, and when done give her a vigorous kick.—*Ex.*

Cows Winter Themselves.

Many farmers are accustomed to dry off their cows early, milking them only about eight months. We think it improves the milking qualities for the cows to milk them ten months, but they should be well fed. We have a neighbour who, ten years ago, found himself short of hay in the fall, and lamenting that he should have to pay out nearly all the product of his cows through the summer, to purchase hay at high prices, to winter them.

He had a moderate amount of straw, and we suggested that the product of his cows from the first day of December, if well fed, would pay for all the corn and meal, middlings, etc., necessary to winter his cows in fine condition. He tried this, keeping account of purchase of feed and sales of butter, and found that the butter came out ten dollars ahead in the spring. This greatly surprised him, as by feeding meal and middlings his cows so increased in milk, that he made $15 worth of butter per cow after the first of December; and he is wont to say that a farmer may have the product of his own cows through the cheese season, and then make them winter themselves. His cows came out in better condition than usual, and he found them much improved the following season. This has been our experience on many trials, and we believe that generous feeding and ten months, milking to be the best system for the dairyman.

But the best system of economizing fodder and working up all the qualities of food raised on the farm, so that nothing goes to waste, everything producing the best result in growth, and beef, milk and wool, is cooking or steaming the food of all our animals. *Live Stock Journal.*

Amount of Butter from a Given Quantity of Milk.

With the view of learning the amount of butter to be obtained from a given quantity of milk, I have recently tried the following experiment at my creamery in Onondaga County, N. Y., where I receive milk from three hundred cows.

The milk delivered at the factory on Saturday evening, July 30th, and Sunday morning, July 31st, amounting to 5,729 pounds, as soon as received, was run into deep cooler pails, and these were set into the tank of spring water. The temperature of this water is maintained uniform at about 53 degrees, by the introduction of an inch stream of water from the spring.

In this vat the pails remained for about 30 hours, when they were removed, in order that by a free exposure to the atmosphere the milk might be soured. It might have produced a better result, if the pails had been allowed to remain immersed in the water until the milk became loppered, but we feared that so long an exposure of the milk and cream to such a degree of cold would cause a bitterness of flavour to the cream and the butter made therefrom.

When about forty-eight hours old, the milk having soured and thickened, the cream was removed and kept until the next day. On Wednesday churning was done in large dash churns, operated by steam power. From this 5,729 pounds of milk, there was produced 232 pounds of butter. This shows an average of 24 69-100 pounds of milk as being required for a pound of butter, very closely meeting the opinion generally held, that two and a half times as much milk is used in making a pound of butter as in producing a pound of cheese. At the season of the year above named a yield of one pound of cured cheese from ten pounds of milk is very satisfactory. This would have produced 573 pounds of cured cheese, from the milk used in this experiment, which gave me 232 pounds of butter.

Cheese at that time was worth 14 cents a pound. Butter, to pay as well as cheese at this price, would need to sell at fully 35 cents a pound, allowing that the material used in making and packing butter cost one half cent per pound more than those required for cheese.

From this loppered milk, which in my case went to the pigs, there is sometimes made a kind of cheese used mainly by the German Jews. The curd is heated to a high temperature, is not salted, but is placed in small bags holding about one-half a pound, and subjected to moderate and long-continued pressure. When removed from this pressure, the cheese is cone shaped, two sides being flattened, salt is rubbed upon the outside and the curing is made in a cool damp place, as is the case with Limburg cheese. There is small demand for this kind of cheese, and if there was a large demand, the prejudice of the Jews will allow them to eat only that which Jewish hands have made. GARDNER B. WEEKS.

Syracuse, N. Y.

Keeping Up Dairy Stock.

Although the demand for dairy cows becomes greater every year, but little attention is paid to breeding them. As a rule, the patrons of cheese factories, and the farmers who send their milk to town to be sold, and who are supposed to have the best milking stock, never raise a calf. In truth, gestation is only allowed for the purpose of enabling the cow to renew her supply of milk. Her progeny is suckled by her only so long as her milk is unsuitable as an article of human food. In some few instances its life is spared till its rennet is in a condition to use for curd. Thus years go by, and a dairy of fifty cows selected for their milking qualities have raised no calves. When these cows become too old to produce a good supply of milk, they are sold or fattened for beef, and their places are supplied by cows raised by neighbouring farmers. In the Eastern States dairies are supplied with fresh stock by animals taken from droves from the West.

Thus it would seem that the best dairy stock of the country is in course of gradual extinction. What extra milkers are produced are the result of accident or sport, since very few are taking any pains to raise stock from those animals in which the hereditary milking qualities are strong. Among grade cattle, size and symmetry are the only two points for which animals are selected to breed from. Even in those breeds of cattle that are famous as milkers, as the Ayrshires and Alderneys, little pains are taken ordinarily, to keep unimpaired the milking qualities of the race. In order to do this it would seem to be necessary to let the calves suckle a long time, and thus protract the season of giving milk. This practice, however, would interfere with keeping the cows in the flesh that is desired in order to exhibit them at fairs, or to have them in good condition to sell.

It is certainly to be regretted that more care is not taken to improve the milking qualities of our stock. Extra milkers should be kept to breed from, their milk not taken so long or in such quantities that they abort their calves, neither should their progeny be killed at such an early age that it is thrown on the dung-hill in order that all the milk of the dam may go to the market or the cheese factory.

It is quite as necessary to raise the calves of good milkers in order to have another race of good milkers as it is to raise the colts of fine trotters in order to have fast horses. Extra dairy stock would bring fancy prices in the market if their milking qualities could be vouched for.—*Prairie Farmer.*

Winter Dairying.

The general impression among farmers who are engaged in the dairy business seems to be that when cold weather sets in, there is no longer any profit in dairying; that the extra feed required to produce the milk, and the greater care necessary to make butter and cheese at this season of the year, render it impossible to follow it with profit. Therefore, many commence to dry up their cows as soon as frost kills the grass, and the stalks and pumpkins are used up. They regard the dairy season as over, and send their cows into winter quarters, which too often means close quarters and a bare living allowance of dry fodder.

Now no dairyman who has had experience in making wintor butter needs to be told that it can be made profitably, and that those who allow their cows to shrink in their milk early in the season, or who dry them up on the first appearance of cold weather, fail to realize a large proportion of the profits that it is possible to make.

It is true that extra feed and care are required for the cows; that with the usual stable conveniences the labour of milking in cold weather is very unpleasant; and that without special preparation and extra care, but a proportionately small quantity of butter, of an inferior quality, will be obtained from the milk. Yet there is no doubt but that, with the proper conveniences for the management of the milk and the requisite experience and knowledge on the part of the dairywoman, as much butter can be made from a given quantity of milk as in the summer, and of a good quality, and that the extra price which such butter will command at that season will more than compensate for the extra food and corn required on the part of the cows. When the farmer fully realizes the importance of furnishing the cows with comfortable stables, and liberal supplies of food, in order to prepare them for the service of the coming season, he will find but little extra food and care necessary to secure a flow of milk up to within two months or six weeks of the time of coming in.

It is urged against winter milking that it overtasks and weakens the cows. This objection is surely a valid one, where the principle followed in wintering is the least possible care and the smallest amount of food that will bring them through in tolerable condition; but where the cows are fed an abundance of good nourishing food, so that the milk makes no drain on the amount needed to maintain bodily heat and animal vitality, the constitution of the cow will not be impaired.

Where an excess of food is furnished over and above what is needed to meet the wants of the animal, and of a proper quality, the milk will make little, if any, draft upon the strength or constitution of the cow. On the other hand, when thus fed and comfortably

housed, even though milked up to a short time before calving again, the cow will usually be in a far better condition for the opening of the coming season than when she has been dried up and wintered in the usual manner.—*Western Farmer.*

Slow Churning Preferable.

The *Scottish Farmer* is unwilling to concede any merit to the newly-invented churns that claim to produce butter so quickly, and argues strongly in favour of the patient, careful mode of churning. It says:

And here we would state that we do not believe in quick or rapid churning. We have, of late, been accustomed to the advertisements of churns, the great merit of which is stated to be that they produce the butter in a very short time. This quickness is very delusive; it conveys the idea that something is gained; but the point is not, is time gained? but is the butter in the condition in which it should be? To do work quickly is not always to do it well; on the contrary, we are inclined to say that, as a rule, good work almost always includes the outlay of patient labour. But this notion of quick churning as the right thing to aim at proceeds from an ignorance of what the points involved in butter making really are. Quickly made butter may be good enough if it is to be used at once, but it will not keep well. The reason is simply this—that all the buttery particles of the cream or milk are encased with thin pellicles of casein or the cheesy particles of the milk; if these are allowed to be in too great a proportion, the butter has that cheesey flavour we all so much dislike, and this will be the case if the churning is done so quickly as to fail to break up or separate the casein pellicles from the oily or buttery particles; this perfect separation can only be effected by slow churning. Of course, there is a medium; but we should be inclined to place the minimum time in which the churning operation is to be kept up at thirty minutes; between this and forty-five or sixty minutes, if the butter "comes," then the quality, other things being equal, will be good.

How to Raise Cows for the Dairy.

"Cattle Breeder," in the *Rural American*, says that a heifer that is designed for the dairy should be brought up with great care, and in a manner that will tend to make her growth, and bring out all her good qualities.

We will suppose that a heifer has been brought up in such a way to the age of 15 months, that she is in a thrifty condition, and has every indication of becoming a good cow. We should recommend that she should now be mated with the bull, as by beginning thus early, we can control in a great measure her future development. As the ensuing five or six years will bring out whatever of dairy quality she may possess, we cannot be too careful at first in our training. And first we should be careful about feeding too high, as heifers kept in high condition are liable to have inflammatory action set up in the udder towards the close of their term, which often destroys the usefulness of a portion of the organ, and tends to hinder the secretion of milk, thereby injuring the future reputation of the cow as a milker.

As there is always more or less of inflammation during the first stages of lactation, the young heifer should be milked as clean as possible at least three times a day, and her food should be light, with sufficient water, until the feverishness is gone, when it will be safe to adopt a more liberal policy.

In the early stages of lactation, cows have a tendency to dispose of their surplus nutrition through the milk secreting organs, consequently they should have a liberal supply of good food at this period, so that not only nature's demands may be met, but that their milk-producing qualities may be stimulated beyond this. In order to accomplish this, we should feed not only all the moist food the cow will bear and assimilate, but whatever of rich food that will have a tendency to produce the largest and best results, always keeping in mind never to impair her digestive powers, nor promote a secretion of fat. The cow that does not respond to such treatment as this should not be kept for dairy purposes, as those cows only are profitable whose milk-producing organs are capable of being improved by judicious feeding.

Hard-Milking Cows.

A correspondent of the *Western Rural* gives the following directions for the cure of a troublesome defect in some cows. He says: "Any one troubled with a hard-milking cow, can remedy it by going to the hen-coop, taking a small feather, and just clipping off the tip end; it will then be handsomely rounded; cut the feather end off, and you have a milking-tube. Get three of them. If you are careful, you can insert these, and old Brin won't know it! Milk the fourth teat; the rest will take care of themselves. If your cow does not milk easy enough, get larger quills. Any cow can be made to discharge her milk by continuing this practice, and she will never know how it was done."

The factory system of cheese-making seems to be gaining ground in England. Its advantages are repeatedly discussed, and in several districts it is being practically tested.

Mrs. Wm. Fowler, of Tuckersmith, has during the season, just ended, with the assistance of her three daughters, made, from twenty-eight cows, $1,075 worth of cheese, besides having supplied a household of fourteen persons with butter, and selling between $75 and $100 worth.

Poultry Yard.

Poultry as Farming Stock.

"How many farmers might obtain lots of new accommodation for poultry by simply making use of the buildings they possess already? and how many farmers consider fowls unworthy of consideration, because of some supposed difficulty or expense in erecting suitable houses? And worse than this, how many farmers try to make poultry pay, without any result beyond continual vexations, merely from lack of ingenuity in bringing ordinary appliances into play? 'Why bother,' they ask, 'about raising chickens in cowsheds and outbuildings, when you can set out as many coops as you like on the grass of a paddock, the gravel of a stable-yard, or upon the scattered rickyard straw?" Because, generally speaking, half your chickens die under the farmyard treatment. They get wet feet, and die of cramp; they drink rain water out of cart ruts, or drink the high-coloured soak-water of manure heaps, of strawyard drainings and other filthy slops, and consequently sicken and die by dozens. We have a troop of adult breeding fowls loose in the farmyard; they pick up a large part of their living there. But they do not thrive so well or keep so healthy as other troops of breeding stock which we have stationed at houses purposely erected in grass fields, far from the homestead. For a very small sum you may knock up a square boarded house, tarred outside, lime-washed inside, and covered with asphalted felt. Each of the four sides is in a separate piece, the roof (if of gable form) in two pieces, all hooked together at the corners by staples and pins. So a house (say six feet or seven feet cube) can be popped into a cart, and temporarily set up in a pasture, on a stubble, or wherever there may be a good picking for the fowls. A couple of perches, a few nests and a drinking pan form the furniture; while the ground covered in by the house (for there is no wooden floor) is spread over with loose earth, ashes and mortar. Such is the home for one cock and eight or ten hens and pullets during the breeding season, or the home of double this number of half-grown chickens. The house should be placed against a hedge, or in a corner where two hedges meet, so that a few poles and posts may protect it against cattle.

There can be no good reason against grazing fowls as well as other "animals;" and the farmer who tries it for the first time will be surprised at the amount of "grub" (literally, perhaps,) which the active scratchers and peckers find in a grass field, in and under the droppings of sheep and cattle, among hedge-roots, upon ditch sides, and so on; only a small supply of grain being necessary twice a day. We wish that many farmers may take our advice—procure what hardy sort you most fancy, Cochins or Brahmas that endure close quarters, game that are strong old English birds, Dorkings that like dry chalk and gravel countries; or, if you are in a low or wet neighbourhood, on a tenacious soil, put a Cochin cock to Dorking females (no cross breeds allowed for parents, mind; but get good blood of pure breeds), and you will have hardihood in your chicks as well as weight and quality in your couples for market."

These suggestions are eminently practical. Small portable poultry houses of the kind recommended, however, are no new feature. In Lord Holmesdale's park at Linton, numbers of these may be seen scattered about the domain, and in one respect they are superior to those suggested by the above extract. Each house is raised about two inches from the ground, resting on the axles of two wooden rollers, so that every few days it can be moved, by the aid of a lever, on to fresh soil, thus avoiding the destruction of the grass underneath, and preserving the air of the roosting house in a constant condition of purity.

In reference to the last suggestion as to rearing hardy table fowl, our experience is much in favour of the converse of the above recommendation, and putting a short-legged Dorking cock to Cochin, or, still better, to dark-pencilled Brahma hens. Size always comes from the female side, and Brahma hens are heavy, hardy and very prolific, to say nothing of their being good sitters and admirable mothers.—*London Field.*

The New York poultry show is announced for December 14th to 22nd. The prize list will be sent to any applicant, by addressing the N. Y. Poultry Society, P. O. box 316, N. Y. City. Entries close on December 3rd.

Buffetting into Friendship.—All sorts of expedients are adopted to prevent fighting when a fresh cock is turned down in a yard. We can suggest a very simple plan, which has the prime merit of being very successful. Tie an empty bag to the end of a long stick, and when the birds are intent on their encounter, buffet them with the bag one after the other. If they are watched for a short time, and this is done whenever they attempt to fight, they will give up their pugilism really from "fear of the sack."—*Canadian Poultry Chronicle*

Fowls Kept in Confined Space should have soft food at least once a day, say first feed in the morning, and plenty of green food; lettuce during the season is excellent, also cabbages; the heads should be thrown whole to the fowls, not chopped, it will afford them employment. Meat should also be supplied, else they may eat each other's feathers. A skewer run through a bullock's livor and then fastened to the ground in the centre of the yard is a capital plan, it enables the birds to pick off the meat in mouthfuls without its being drawn all over their yard. A change of food occasionally is always desirable.—*Canadian Poultry Chronicle.*

Horticulture.

EDITOR—D. W. BEADLE,
CORRESPONDING MEMBER OF THE ROYAL HORTICULTURAL SOCIETY, ENGLAND.

Vine Culture.

To the Editor.

Sir,—Having noticed two or three articles in former numbers upon the science of grape oulture, I beg leave to make a few remarks upon the same. Now I differ somewhat from Mr. G., as he advises people to grow wild vines in preference to what he calls foreign varieties. Everyone knows that, whatever fruit is planted in its wild state, it will remain so for ever; and be sure the grape is no exception to the rule. Why go to the trouble of grafting, inarching, or budding the wild sorts of fruits with superior sorts, if merely planting a few cuttings will improve them, so as to be better for new beginners than imported and improved varieties? If our friend had advised grafting or inarching some of the hardiest of our imported varieties on the wild stock, I think he would have been nearer the mark. But the proper way to get grapes suitable for the climate is from seed sown from good hardy grapes crossed with some high flavoured variety. This requires both care and knowledge, which I will explain in another number.

Then again Mr. G. says that cuttings, as he describes, are much better than vines grown from eyes. There I must differ from him, as I am sure every good grape grower does. Vines grown from eyes properly managed make the very best you can possibly get.

I have made the vine my study for years, in fact I have been amongst them nearly all my life, and there is no way of propagating the vine that I have not practised; consequently, I know which is the best way to manage them for profit. I have trained them in every way that a vine could be trained, and I know our friend G.'s style has the advantage of wanting no trellis; but if they were very heavily laden with fruit, and had to encounter a storm with a heavy wind, they would all be broken to pieces, and vines and fruit all spoiled together. My name is well known as a grape grower in Covent Garden Market, London, England, for I have taken tons upon tons there, which have frequently brought ten and twelve shillings per pound, the earliest of them; and I never sold a pound under 2s. 6d. per pound, when all the grapes of the continent of Europe were coming into market by ship loads. I am convinced that vines grown from eyes are the very best that it is possible to get. I will explain the whole process of propagation in another paper, because it is of great consequence to the planter, for he can be getting his vines strong while he is getting his vineyard ready to receive them, and if they are well managed it will make two seasons difference to him in fruiting of them, which is of great consequence to his pocket. I also think that Mr. G. is inclined to be too cheap with ploughing and trench-ploughing the vineyard, etc.

I am convinced from my own observation and experience that excellent grapes can be grown in Canada, but it is not every one that will succeed with them. The land is not all suited to the vine, neither does every one know sufficient about them; and they will not find out all the little secrets from reading articles in the newspapers; it requires practice as well. I am certain it will pay a higher percentage to those who succeed than any other crop that can be grown; but I think our friend painted it in too glowing colours. A seven-year old vineyard is put down at three pounds for ploughing, harrowing, hoeing, pruning and so forth. Now as many of our readers don't know the work that is required, I will name some of the items requisite to produce good fruit. Firstly, the autumn pruning, then spring cleaning up with the plough or otherwise. I have omitted the fall cleaning, but that is quite as requisite as the spring. As soon as the vines are fairly broken they want disbudding, that is, all the superfluous shoots broken off, so that nothing but good sound bearing shoots are left to carry the crop. Then as soon as the bunches show themselves, there is the stopping process, that is, pinching the fruit-bearing shoots in to one or two leaves beyond the fruit; then the laterals all want stopping. All these operations require going over several times, as it will not do to be too severe on them all at once—besides, the shoots will not show themselves all at once. Then when the vines have blossomed and the fruit is set and beginning to grow, say the size of No. 4 shot or very small peas, take your scissors and thin the grapes out—begin early enough, for you cannot well thin them too much—for the more room they have the finer they will be, and you will have more weight than you would by letting them stop without thinning. Besides, the fruit will be so much better in quality, that it will fetch more than double the price that those will that are left to themselves.

You shall hear from me again soon, with the editor's permission. I should like to correspond with some vine dresser on the subject. I have just arrived from England.

GEO. HENRY COLLOP.

Richmond Road, Ottawa.

Note by Editor.—These views of our correspondent need some modification for the profitable culture of the grape in the *open air* in this climate, as he will discover before he has brought ten acres into full bearing and sold them in the Ottawa Market.

The Grape Crop of 1870.

From what we have seen and heard during the past few weeks, at the various agricultural fairs held this fall, the year 1870 seems to have proved one of the best and most favourable to grape growing we have ever had in Canada. The unusual excess of heat and sunshine during August and September caused the grape to commence colouring some two weeks earlier than usual, and the absence of frost till late in October enabled every grower to gather his crop of grapes in a fully ripened condition. At the Clair House vineyard, near Cooksville, the entire crop of grapes, 20 acres, not only ripened well, but the yield of must was large and the quality much superior to the average of seasons. Even the Catawba, a grape that rarely gets ripe there, is this year fully ripened.

That grapes can be grown and wine made from them in Canada has been fully demonstrated at Clair House, and with the large outlay incurred and appliances put up, we may expect that an article of first-rate excellence will be produced there. An experiment made of stripping the grapes from the stalks previous to being pressed, showed that a much finer, richer, and more highly coloured must could be obtained than under the usual process of pressing grapes and stalks together. As only the best and cleanest grapes are used for wine making, the must from the others being distilled into brandy, there ought to be wines of the highest quality of excellence obtained. The Clinton grape is the one mostly grown, with some Concords, Delawares, Isabellas and Catawbas, but other kinds are being used as fast as the vines come into bearing, and another year or two will test the merits of some of the new sorts for wine making. J. M.

Raspberries.

The editor of the *Small Fruit Recorder* tells the readers of that interesting and instructive paper that at South Bend, Indiana, the following results are noted in the different varieties named below:

Seneca Black Cap.—The finest distinct black sort. Wonderfully productive, and this season kept in bearing the latest of all. Very superior quality; sells quick. Perfectly hardy and reliable.

Philadelphia.—Hardy; enormously prolific. One of the most reliable.

Clark.—Very hardy and vigorous. Firmer than the last, and better colour, netting nearly as much money from the crop, although not so prolific. Very sweet and delicious.

Mammoth Cluster.—"Ahead of the heap." Immensely productive. The bunches bent to the ground with the load of largest-sized fruit. Pulpy and delicious. In great demand on account of its very sweet and delicious flavour.

Naomi.—Proves hardy, while the Franconia kills down by its side, thus showing them to be distinct varieties. Very large, delicious and productive.

Golden Thornless.—Can't be too highly extolled for productiveness, hardiness and beauty of fruit. A great favourite.

The reader will remember that the soil on which these plants grow is very light sand.

A writer in the same paper, speaking of raspberries at Palmyra, N. Y., says:

Among our standard reliable sorts, I would name Davidson's Thornless, Seneca, and Mammoth Cluster, as taking the lead for profit and table use of the black kind; and of the red, Clark, Philadelphia and Kirtland. The Seneca sold for the highest prices on account of its fine uniform size and coal black colour, besides yielding a week after other kinds were gone. It certainly keeps in bearing longer than any other, whilst its first pickings were made nearly as soon as the Doolittle. The Mammoth Cluster has no equal for productiveness and large size of fruit, and very sweet, delicious flavour. Another important point in its favour is that it bears just as well on four-year old bushes as these younger. This is of great importance.

The Davidson Thornless should be in every garden. It is deliciously sweet and juicy. Very productive and *very* early.

The Clark is a magnificent red raspberry, very hardy, never having been hurt by the winter. Fruit large size, and sufficiently fine (if picked as soon as it turns) to carry two to three hundred miles. Its high scarlet colour and most delicious flavour give it a good sale. For home use nothing excels it.

Philadelphia and Kirtland we have often given our opinion of. Suffice it to say that our faith in them is not abated in the least.

The Naomi is a magnificent red variety. Very firm, exceedingly productive, beautiful shape, uniformly large size, high colour, delicious, and bush perfectly hardy. It is certainly a different berry from the Franconia.

The Golden Thornless has astonished all who have seen it. Bushes loaded to the ground with wonderful large and beautiful dark golden fruit. If gathered as soon as they turn they are very good, but if allowed to remain on until "dead" ripe, they lose their flavour, and have a dirty, unnatural appearance. We are confident they will become one of the most profitable for drying.

The Lum's fall bearing, or "ever-bearing," and Catawissa are very valuable as fall bearers—especially in sections where peaches cannot be grown. To have them yield large crops the tops should all be cut off just as winter sets in, and a large lot of coarse manure thrown right over the crown. Leave this on in the spring, and allow the new growth to come right up through, and when this gets *not to exceed* two feet high, nip off the tip ends, so that they will branch out freely, for let it be remembered, that those varieties yield the bulk of their crop on about six or eight inches of the top of each cane. So that the more tips they have the greater the crop. Moisture is what they delight in, hence the necessity of heavy mulch.

The Black Raspberry—General Directions for its Cultivation.

Since the several varieties of the improved Black Raspberries have become so deservedly popular, not for domestic use alone, but for the general market also, it occurs to me that perhaps some specific directions for their cultivation would be received with favour by many of the numerous readers of the horticultural department of your excellent journal. Having made its cultivation and development a specialty for the space of nine years last past, I will submit the following summary:—

It will require 1,800 to 2,000 plants to set a single acre of land. Any good soil adapted to the production of corn or potatoes may be used. A position shielded from the range of heavy winds would be preferable. A partial shade, as a young orchard, is no impediment.

In the fall or early spring prepare your ground as for corn or potatoes, then proceed to strike furrows in the direction you wish the rows to run, seven feet apart, three inches deep, leaving the bottom of the furrow broad and level. Cross-mark with corn-marker three and a half feet apart, and in planting place a plant at each crossing, carefully spreading the small fibres out in the furrow, with the sprout or germ upward, then with the hoe carefully cover all the roots with fine soil two inches deep. After this, with cultivator and hoe, see that neither grass nor weeds are allowed to grow. A crop of early corn, potatoes, beans, or what is more profitable, strawberries, may be grown between the rows the first season without detriment.

They will need no pruning the first summer. Let the whole growth trail on the ground, and during the latter half of August, and through September, attention should be directed to layering the tips for the purpose of producing a valuable crop of plants. When the tips of the trailing vines seem swollen, and become naked or free from leaves, of a reddish colour, and semi-transparent, they are ready for laying, the proper mode of doing which is, with the corner of a hoe excavate the soil under the tip, letting it fall into the cavity, and replacing the soil, pressing all lightly with the foot or hoe. This causes the germ of the future plant to form from, or grow out of the extreme tip or point of the young cane or brier.

And this is the only true process of propagating black raspberry plants, but when thus treated, each plant will multiply itself from ten to thirty fold the first season after

setting; the value of which exceeds that of a crop of fruit.

The following spring, after the young plants are all removed from the ground, cut off the ends of the previous season's growth, to within one and a half to two feet of the root—it may seem wasteful, but is necessary to be done—thereby, the size of the fruit is increased, and the labour of harvesting is greatly diminished.

There will now spring up large upright canes for the next season's fruiting; these, when one and a half to two feet high, in the latter half of June, should be cut or pinched off at the tips. This causes numerous side branches to start, and the main canes to grow more stocky, which prevents their being blown down by the wind, and also the necessity for staking and tying up to support the next crop of fruit. The following winter or early spring these side branches also should be cut off, at least one-third to half their length, and then such shallow cultivation as is sufficient to keep the weeds and grass subdued, is all that is needed till after the fruit is gathered, when all the old bushes may be cut away, and the ground thoroughly cultivated, or ploughed, not too deeply, turning the furrows toward the rows. And after this, in each year, the same course of treatment is advisable.

No pinching nor cutting back of the young canes after the first of July.

In gathering berries for market, see that all are fully ripe—partially ripened fruit becomes soft and sour in much less time than it does when well ripened before being packed. Ventilated quart or pint boxes, not more than three inches deep, square in form, with bottoms elevated, so as to pack one upon the other, without shelves or drawers, are preferable for packing. The ordinary yield of the improved varieties of black raspberries is about 2,000 quarts per acre. But with labour and skill bestowed to that end, more than double that amount is not unfrequently gathered from a single acre in one season. A good picker often gathers 75 to 85 quarts in one day, but 50 quarts would be considered a good day's work in good picking, and 35 quarts would be a fair average during the ordinary season for berries.

In conclusion, in commendation of the improved varieties of the black raspberries as adapted to profitable cultivation, I am free to affirm that they have indeed most valuable qualities; they need no covering nor winter protection, do not fill the ground with suckers, are great bearers, and the fruit is so firm that it can be shipped to our most distant markets in good condition, and invariably finds a ready sale at highly remunerative prices.—*Utica Herald.*

KEEPING PLUMS.—"H. G." asks, "Can you inform me of the best plan to keep plums fresh for a length of time, after being ripe?" Will some one who knows how please reply to this inquiry?

The Work Done by a Leaf.

Now, what does it do? It pumps water from the ground through the thousands of tubes in the stem of the tree (the tubes which itself has made) and sends it into the atmosphere in the form of unseen mist, to be condensed and fall in showers—the very water that, were it not for the leaf, would sink in the earth, and find its way perchance through subterranean channels to the sea. And thus it is that we see it works to give us the "early and the latter rain." It works to send the rills and streams, like lines of silver, adown the mountain and across the plain. It works to pour down the larger brooks which turn the wheel that energises machinery which gives employment to millions. And thus a thousand wants are supplied, commerce stimulated, wealth accumulated, and intelligence disseminated through the agency of this wealth. The leaf does it all.

It has been demonstrated that every square inch of leaf lifts 3-500th of an ounce every twenty-four hours. Now, a large forest tree has about five acres of foliage, or 6,272,640 square inches. This being multiplied by 3-500th (the amount pumped by every inch) gives us the result—2,352 ounces or 1,176 quarts, or 294 gallons, or 8 barrels, a medium-sized forest tree about 5 barrels. The trees on an acre give 800 barrels in 24 hours. An acre of grass, or clover, or grain would yield about the same result.

The leaf is a worker, too, in another field of labour, where we seldom look, where it exhibits its unselfishness—where it works for the good of man in a most wonderful manner. It carries immense quantities of electricity from the earth to the cloude, and from the clouds to the earth. Rather dangerous business, transporting lightning. I think it would be considered contraband by the "U.S.," or "Merchants' Union," or any common carriers, but it is particularly fitted for this work. Did you ever see a leaf entire as to its edges? It is always pointed, and these points, whether they be large or small, are just fitted to handle this dangerous agent. These tiny fingers seize upon and carry it away with ease and wonderful despatch. There must be no delay; it is "time freight." True, sometimes it gathers up more than the trunk can carry; and in the attempt to crowd and pack the baggage the trunk gets terribly shattered, and we say that lightning struck the tree. But it had been struck a thousand times before. This time it was overworked.

As we rub a stick of sealing-wax or a glass tube with a warm silk handkerchief, so the air is always rubbing over the face of the earth with more or less rapidity. And what a huge electrical machine. But be not afraid—the leaf will see that it is taken care of. As we guard our roofs from the destructive action of lightning—dashing to the earth, crashing, rending, burning on its way—by erecting the lightning rod, whose bristling points quietly drain the clouds, or failing to do this, receive the charge and bear it harmless to the earth—so God has made a living conductor in every pointed leaf, in every blade of grass. It is said that a common blade of grass, pointed by Nature's exquisite workmanship, is three times as effectual as the finest cambric needle, and a single twig of leaves is far more efficient than the metallic points of the best constructed rod. What, then, must be the agency of a single forest in disarming the forces of the storm of their terror?

Nature furnishes the lightning, and it furnishes the lightning rods. Take a hint, then, and plant trees.—*The American Entomologist and Botanist.*

Wide Planting and Long Pruning the Grape.

As so much failure has resulted in planting vines so close to each other, and from the practice of cutting away the wood to from two to four canes if long pruning is practised, or to spurs if spur pruning is the system adopted, let new beginners in planting a vineyard set their grapes from eight to twelve feet apart in the rows, having regard to the richness of the soil and the character of the vine as a rank or moderate grower; let the trellises be six and a half or seven feet in height, with five wires. When the vines have fully covered the trellises, and are impatient of restraint, let the vigneron take out alternate vines, leaving the others from sixteen to twenty-four feet distant from each other in the rows.

Perform the first pruning in the fall or winter, cutting away some of the tangled mass of the wood, but leaving three times as much as would seem to be required. Do nothing more with the vines till the early days of summer. In the meantime the buds burst, and shoots push out, the leaves develop and the fruit clusters appear; and as not a few but very many buds are left to receive the life-giving currents proceeding from a large and strong root, vegetation proceeds in its normal course, and there will be strength and vigour, and not weakness and decay, in the progress it will have made. It is during the critical period of the starting of vegetation that nature should encounter nothing to disturb the performance of her functions, and this period having passed, when the clusters have appeared, the time comes when the real work of pruning may be done.

Surveying the trellises, the cultivator will no doubt see fruit clusters in excess; whereas, in case of deficiency, he would have no remedy. Have the courage to cut when cutting is attended with no danger, even though scores and scores of clusters of incipient fruit are thereby made to come to naught. The planter may remove entire canes, then

entire shoots, until he is satisfied that they may have no more fruit than they will have leaves to ripen. This completed, the canes, and from time to time, the shoots, are brought up, and secured to the trellis wires. No summer pruning or pinching is to be resorted to, and nature proceeds with the work of maturing the fruit.

Many grapes treated in this way have been found free from disease; whilst others planted in the same kind of soil, but which have been pruned in accordance with the ordinary method, have been badly stricken with mildew.—*Journal of Horticulture.*

NOTE BY THE HORT. EDITOR.—We heartily endorse so much of the above article as relates to wide planting, and long pruning, without summer pruning; but we fail to be able to appreciate the necessity of fall or winter pruning, and believe that it can only be advocated on the ground of convenience, the spring being so short that it is a great gain to do all that can be done before the rush of spring work comes on. However, if fall or winter pruning is to be done, we would most heartily commend the course above suggested, for it is not safe in this climate to prune close in the fall. But we see no reason why the whole pruning can not be done in the early spring, in March in some places and seasons, in April in othere. The idea that the vine can not be safely pruned at that time is giving way before the test of experience; and the fine-sounding expressions about "the critical period of the starting of vegetation," etc., etc., are to be considered merely as rhetorical flourishes.

Vine Culture and Garden Talk.

Some time since, when giving a description of our wire fences for vines, and application of manure to them, I promised to state results, as well as part of the process, in some future communication. Our vines are Hartford Prolific, Delaware, Black Cluster, Concord and Isabella, several of each kind.

Our course of training has hitherto been to nail the vine to a board fence having a southern aspect. This fence blew down last spring, and we substituted heavy wires, strained from post to post, the posts nicely planed and pitched at bottom to prevent decay, and placed about twelve feet apart. We consider, after this summer's trial, that the wire does not answer so well for the fruit as the board fence, but the appearance is very pleasing. The fruit sets better against the boards, and is somewhat earlier, but our manure is peculiar and our stronghold, and consists of nightsoil pumped direct from the vault, and poured all around the vines, on earth previously loosened with the fork, to the extent in surface of about six feet square, and in quantities of about six pailsful to each vine. This is the third year we have used this manure in this manner, and our success is most complete, notwithstanding the absence of the fence on which to train the vines. We have had a most excellent crop, and the quality has been pronounced by good judges as quite equal to hothouse grapes; indeed some preferred the fine fresh flavour of those grown in the open air with us to that of the hothouse production.

We attribute the quality as well as quantity, entirely to the manure, and the shoots for another year are really prodigious, many of them being twenty feet long, and some as thick as the forefinger of the hand—and I have rather a large heavy one, having of late years done a good deal of work with it. We are now fully convinced that the plan we have adopted is good, and works to perfection. We have a large puncheon sunk in the earth, and therefore quite tight, from which we pump every fall, about November, 70 to 80 pailsful of soil, and distribute as before described. I am sure we have gathered at least 250 pounds of grapes off our vines, 12 in number, and extending 170 feet in length. At 15c. a pound wholesale, the produce would have been worth nearly $40 to purchase. But it has always been a maxim of ours that any luxury that we can produce may be used *ad libitum*. We are economical enough in all we cannot raise, but we consider, where a little extra care or attention, combined with industry, can furnish luxuries in abundance, we have a full right to enjoy the result without stint.

This principle works well in any family, and is a source of much contentment under some deprivation in things we cannot raise, and of great enjoyment in others that we can. There is to us great satisfaction in seeing our friends feast on such home productions, and we heartily advise our brother farmers to cultivate the same feeling, and at the same time add to their store of enjoyment any luxuries that may be within their reach on these terms. These little matters make home what home should be to every family—a place to look back upon in after life as one of sunshine and comfort; and when hereafter, our children are singing some of the old and beautiful songs that men of taste and refinement have written and will yet write on home and its surroundings, what if it does bring the water into a strong man's eyes at the retrospective thought?—there are few men, and no woman, young or old, but would readily forgive and appreciate it.

Whilst on the subject of the garden, I may mention the large size of our apples. We have two trees that produce many barrels, and nnmbers of these apples measure 13 inches in circumference, and some weigh 1¼ pounds. Of course, this great weight is not attained by many,

Our young trees, planted out only four clear years, bore pretty well last year and this also, but the dry spring caused bushels of little apples, the size of nuts and walnuts, to fall off before coming to maturity. Three or four of our best young standard and dwarf pear trees have died down to the root without any apparent reason. The leaves turned quite black a month since, and the trees seem sure to die.

If any of your correspondents can give some advice for the prevention or explain the cause of this, they would certainly merit and receive our best thanks, as I fear the same disorder will extend to the rest of our orchard, and I am getting too old to afford time to plant young trees much longer for me to hope to see them bear fruit; but my children may, and one of the comforts of a farm and garden is that hereafter your children will look back on the plantation as the work of their father's hand, and no doubt the recollection will be as pleasant to them as the prospect is to the father. So we will plant away as long as we live; some one will be here to enjoy it, and our children may thus be induced never to part with the homestead, on which we have spent so much personal exertion for them. C.

Twitchell's Acidometer.

The able editor of the *Grape Culturist*, published at St. Louis, Mo., states in the September number that he has submitted one of these instruments to a thorough trial on some eight varieties of wines, and after this test of its usefulness confidently recommends it as the only safe and practical instrument of the kind he has seen, and which any person of common intelligence can use with perfect safety. The action of this instrument is based upon the well-established fact that where an excess of carbonate is added to a liquid containing an acid, there will be given off carbonic acid gas in exact proportion to the amount of acid there was in the liquid. This instrument is so made that the exact amount of acid in the liquid can be read off from a graduated scale, without any calculations or corrections. It fills a much felt want, and should be in the hands of every careful wine maker, and we notice it now so that those who are interested in this matter can supply themselves in season for the present vintage.

Blackberries.

The experience of another season seems to be in favour of the Kittatinny, on account of its ability to endure the climate, and the large crop of handsome fruit. It is a most vigorous grower, and throws up numerous suckers, which require to be kept under. The canes should be kept pinched back to a height of four feet, and have plenty of room to branch out, and the branches be also pinched in at three feet. The canes are armed with fearful thorns, but this is true of all, and we must put up with them until some person introduces a really valuable blackberry without thorns.

Keeping Grapes Fresh for Winter Use.

If you desire delicious, fresh grapes in winter, or even up to the next spring, they can be had by a very little expense. Pick the bunches only on a dry, warm day, and place them in a cool, shady place for at least three days; then commence to pack them in paper boxes that will hold about ten pounds. Between each layer of grapes place a single thickness of newspaper; the boxes should not contain more than three layers in thickness. Then place in a cool, dry room—not in a cellar, for the *natural* dampness there will cause mould and decay. In this way the past very damp season we kept Concord, Delaware, Hartford and Diana, the last being in good condition in March.—*Rural World.*

A Word for the Toad.

During the past week the Striped Potato-bug (*Lytta vittata*) came into my potato-patch, and in two days defoliated about a thousand hills, when four of us set to work gathering them. In one hour we gathered a full gallon. Where did such a quantity of these bugs come from in so short a time? But the most curious part is to come? A black boy who was helping me said he did not like to gather the bugs, because wherever they were numerous he found a lot of toads, and he was afraid of toads. This attracted my attention, as I had seen a number of toads myself, and, to my surprise, I found that they were eating the bugs. One fellow ate twelve bugs, at the rate of four per minute. He would not eat any faster, although we ran the bugs all around and over him. Has any one else noticed this? It is certainly new to me, for I did not think anything would eat these Blister Beetles. The Ladybird is shy of them, and so far as I have observed, none of the common cannibal beetles will attack them.—S. F. T., Hannibal, Mo., in *Am. Entomologist.*

Horticultural Notes.

To the Editor.

SIR,—I have noticed through the summer many complaints about mice girdling apple trees. I have never lost a tree from this cause, since I adopted, some sixteen years ago, the very simple plan of putting strips of cedar bark, or bits of shingles, round the trunk, which I do every autumn and remove them in spring. I just put them up round the trunk, touching the ground, and tie the strips with a string. Any little boy or girl could cover an orchard in a day, and the same strips will do for years. I have only some two dozen of trees, and do the job myself.

This has been the most extraordinary season for vermin I ever remember. Squirrels and chipmunks ate all my strawberries, and a third of my gooseberries. Field mice tried everything; they destroyed a great many dwarf peas, and carrots, turnips, beet root, and savoy cabbage. There was a great crop of plums, but they rotted *in bunches*. I examined the rot closely, and it was evidently a very rapid decay, no insect being visible. Our apples, too, rotted, and there are some kinds with worm holes in almost every apple. I never noticed either plum or apple rot till last year; the worms are old acquaintances. I caught a good many of the vermin in rat traps. There is one very valuable vegetable, namely rhubarb, which no animal ever injures, and it is in my opinion about the most useful and I believe most wholesome plant in the garden; and this year it was good till September, having been first pulled the last week of April.

I noticed the doings of the curculio, but all the damage they did was very small. I think some of the birds pierce the fallen plums for the purpose of eating the curculio, as I noticed many of them with big holes in them and the worm gone. I have always lots of birds, and I do not grudge them all they steal, as their music and the good service they do in eating insects, and their pretty cheerful ways, far more than compensate for any mischief they do.

One family of squirrels was brought up about the house somewhere, as one morning five little fellows were descried sitting in the tin pipe at the eaves of the roof, and three of them were murdered before they got fairly launched in the world. It was cruel, I daresay, but they are awful little thieves. I had a nice row of crocuses, and the little villains carried off every one just when they were about ready to remove for the summer. They did not meddle with the tulips just in the same place. I found the helleboro most effectual on the currant and gooseberry trees, but I think I had to administer one or two doses every fortnight during the whole summer. Still I saved my fruit, and half an hour or so in a summer morning will suffice for the purpose.

I didn't mean to spin so long a yarn when I began, and I hope you will excuse it.

Fergus, 28th October, 1870. F.

Fall Bearing Raspberries.

Mr. U. H. Davies has sent us some ripe raspberries, gathered on the 12th of October, and which he found growing near the G. W. Railway track in the vicinity of Woodstock, and says that he has lived in Canada forty-four years and never before met with such a phenomenon.

There are many varieties of fall bearing raspberries, some of which are cultivated in our gardens, but they are none of them of much value when grapes are abundant. We are satisfied with raspberries in their regular season, and do not care to return to them when pears, grapes and apples have become abundant.

Protection against Mice.

To the Editor.

SIR,—The annual loss sustained by the ravages of mice among fruit trees all over the country, during the winter months, makes it a question of considerable importance, how we may cheaply and effectually protect them from being girdled. The importance of this subject will be deemed a sufficient apology for laying before your readers my plan for accomplishing this desirable object.

I use well-burnt round tiles, such as are used in under-draining, four inches in diameter by fourteen inches long, divided lengthwise in two equal parts. Clearing away the dirt two inches deep from each tree, these pieces are brought together around each tree, fastening their tops with a piece of wire and drawing the dirt around against them, and pressing with the foot, the work is done. If they are properly burnt these tiles will stand many years.

Two boys will thus protect several hundred trees in a day, costing in all two and a quarter cents a tree. The above-sized tiles were bought from Mr. Campbell, of Hamilton, for twenty dollars per thousand, that is, two thousand pieces. May I request that if you are aware of a more effectual plan you will publish it.

W. H. MILLS.

Orchard not Bearing.

To the Editor.

SIR,—You would confer a favour by giving me information on the following subject, either by letter or through the columns of your valuable journal. Eight years ago I set out some standard apple trees pretty late in the spring, since which time they have grown steadily each season, so that now they spread out from ten to twenty feet in diameter, and yet they bear no fruit, at least, not till this season, when there were a few apples on some of them. They all appear to run to wood in growth. What I want to know is, how can I check this rapid growth and cause them to bear, without injuring the trees? Last year I pruned them well, but still the growth seems as rapid as ever, without yielding fruit.

By replying to the above you will greatly oblige an old subscriber.

Lucan. S. CLATTERHAM.

REPLY.—Seed down the orchard for a few years, and the growth of wood will be checked and fruit buds will form.

MILDEW ON ROSES.—A correspondent of the *Cottage Gardener* gives the following cure for mildew on roses: Rub down in a gallon of soft water one pound of soft soap; with the solution syringe the upper and under surface of the foliage, and the mildew will disappear as if by magic.

THE CARPET CHAMOMILE.—This plant will make a good turf, as it spreads fast, and grows freely on all soils, even the poorest, while it is not affected by the hottest sun or the most severe drought.

A correspondent of the *New England Farmer* says that last year he saved his onions from the maggot by removing the earth from the bulbs with his fingers, being careful not to disturb the roots while weeding them. A pound of copperas dissolved in a pailful of soft soap, and, when thinned with water, applied to the onions, is good to keep off the maggot, and to promote the growth of the onions.

Tilton's Journal of Horticulture for November has been received, and is fully up to its usual standard of excellence. The illustrations and descriptions of new things are alone worth the subscription, and as the price is to be reduced from $3 00 to $1 50 after this year, every one can afford to take it. Publishers offer very liberal inducements for making clubs. J. E. Tilton & Co., Boston, will send to any address a sample copy and premium list.

THE TROPHY TOMATO.—It is without exception the best and most perfect tomato we have ever seen. "As heavy as a stone," is the expression of those who have examined it on our grounds. Certainly we never saw its equal in size, beauty, uniformity, solidity and goodness. In cutting it one is reminded of an old cheese. There are no open cavities in it. The slices, when cut and laid upon a dish, are as perfect as the slice of a potato. The flavour is deliciously sweet. The average weight, 1lb.; many weigh from 1½ to 1¾lbs.—*The Small Fruit Recorder.*

SPLIT TREES.—W. A. Gordon, of Wardsville, writes:—"About twelve months since you advised me respecting the bolting of split trees with iron bolts. I have tried on two; one of them is a perfect success, the other has half of it dead. As to the cause of death I have two opinions; first, it had been rent a long time; second, I bolted it right through the heart. In the other tree the bolt is about an inch from the centre of the stock, which I believe is a good plan."

DISEASED PEAR-TREE—H. Thompson sends a sprig of a pear-tree, with an enquiry as to the cause and proper treatment of the diseased condition. The leaves have been attacked by a fungus, a small parasitic plant, growing on the under side of the leaves. Flour of sulphur is destructive to most microscopic fungi, and if it should appear on the leaves next year, a quantity of sulphur may be sprinkled on the surface of the ground as far as the branches extend, and dusted through the leaves. This should be done as soon as the first appearance of anything can be detected on the leaves, else it will be too late.

SOWING LAWN GRASS SEED.—"Essa" is informed that the best time for sowing lawn grass seed in this climate is the spring.

Correspondence.

Sugar Beet Seed.

Mr. H. L. Smith, of Parry Sound, asks where he can obtain genuine Silesian Sugar Beet Seed, and huw many pounds it takes to an acre, to sow in drills 2½ feet apart?

There are several kinds of sugar beet seed. Many prefer the white Silesian, but in some factories on the Continent several other sorts are as much thought of, and used. Much depends on the sort of land on which the seed is to be sown. An application to any of the first-class seedsmen of the principal cities in Canada will ensure a genuine article. As Mr. Smith writes from Parry Sound, we suppose his nearest point of supply will be Toronto. Messrs. C. Dawbarn, Simmers, or Fleming, wholesale seedsmen of this city, can furnish reliable qualities and in any quantity that may be required, provided the order reach them early enough to get the supply from home, before the spring opens. We should advise an early application to one of these firms, desiring them to furnish a quantity of each kind that has been found to answer by their correspondents in Europe. Our enquirer will then have an opportunity of testing three or four varieties as adapted to his soil and climate. About 6lbs. will sow an acre, and be sure of a sufficiently thick plant, allowing for some to be imperfect seed. Of course, one-half this quantity will suffice, provided it all grows; but all the mangel tribe are very liable to miss growing, and thus leave large gaps in the rows About the beginning of June is the best time to sow; this has been proved, by many experiments, to produce the best roots with most sugar per ton.

Pedigrees of Exhibition Animals.

Several enquiries have been addressed to us in reference to this subject. One correspondent asks whether he complied with the resolution of his Agricultural Society that "Exhibitors of thorough-bred stock hand in pedigrees of the same to the President on the morning of the show," by handing in a certificate of the record in the Herd Book. With regard to this enquiry we should answer that literally he did not, but in effect he did, as the certificate of record and the Herd Book would supply the necessary information.

Another correspondent complains that the judges refused to accept or look at a copy of pedigree, and wishes to know whether a judge should "understand, examine, and be influenced by pedigrees?" We think there can be no question but that the pedigree should be taken into account in awarding prizes. It is not customary, nor is it always necessary for the judge to examine pedigrees. That is generally done, if required, when the entry is made; and the judge may take it for granted, if an animal is admitted to competition in a thoroughbred class, that the pedigree is satisfactory. But where two animals approximate very nearly in merit, as to points of excellence, the consideration of their respective pedigrees should certainly be allowed due influence in coming to a decision. It is an element of *primary* importance.

Natural History Query.

E. C., Cobourg, writes, "Can you or any of your readers inform me whether there is any book published exclusively on Canadian birds; if there is, where I can get one? And can you tell me the name and species of a bird which lays its egg in other birds' nests? The colour of the egg is white with blackish brown spots; the nests in which the eggs were laid belonged to small birds, and the eggs were much smaller. I have found five or six of them, but never more than one egg in each nest."

There is no book of the kind published in English, but a work in French on the subject was published some time ago. The bird whose cuckoo-habits are referred to is the Cow bird (*molothrus pecoris*), one of the family of starlings, of which the oriole, bobo-link, and meadow lark are also members.

Coal Tar and Crude Petroleum for Roofing.

"W. H." inquires the best mode of applying coal or gas tar to roofs. The only effectual mode of using it is to heat it to the boiling point, and apply it with a brush, taking care to allow the heat to subside until it will *not burn* a feather, or the brush will be spoiled. The outside coating of tar will all come off in a year or two, as such is the effect of light and exposure to the air and elements; but as it penetrates into the pores of the wood of the shingles, when applied boiling hot, the portion so absorbed will never wear away, and the shingles will be preserved to a great degree from decay. The price by the barrel at the Gas Works is about ten cents per gallon, exclusive of the barrel.

As to the value of crude petroleum as a coating to shingles, there cannot be two opinions as to its increasing their durability; and the outside when exposed to the elements will not be affected in the same manner, or to any such extent, as if coal tar be used. But its extreme inflammability renders its value very doubtful when all the disadvantages are taken into account. Rain-water could not be used for many months from a roof so covered, on account of the strong effluvium arising therefrom.

Scheele's Green.

To the Editor.

SIR,—A word as to the employment of this poison as a beetle destroyer.

Without going deeply into the chemistry of the matter, I may allude to the fallacy of supposing that, because offensive and poisonous vegetable substances are neutralized and utilized in the processes of vegetation, therefore mineral poisons can be so neutralized.

The fact is that many of these vegetable substances consist of perfectly harmless chemical elements, owing their virus to their mode of combination, which virus is destroyed by the changes which they undergo during the growth of a crop. But mineral poisons frequently enter unchanged from the soil into the plant, and thence into the animal which eats it. And it is worth trying by actual experiment whether arsenic (which essentially cumulative poison enters nto Scheele's Green in combination with the corrosive poison of copper) does or does not pass from the soil into the tissues of plants. As a case in point, and recorded in the transactions of the Royal Dublin Society, I may mention that my cousin, Mr. John G. Rathbone, found that some sheep on a farm of his, four miles from Dublin, were diseased from eating turnips, which had been manured with superphosphate of lime. Analysis showed that a mineral poison (which I am almost certain was arsenic) had made its way from the superphosphate to the turnips, and thence to the sheep. It may be worth while stopping the dreaded beetle even at the hazard of a partial poisoning of frontier farms; but still it is worth determining by actual experiment whether either of the two poisonous elements in Scheele's Green can pass into the tissues of a plant.

Any one having a green-house or hot-house could transplant some rooted plants into a box manured with Scheele's Green, and then in the spring analyze the leaves and roots of the plants. The presence of arsenic, even in very small quantities, would show itself by the usual delicate tests.

W. E. HAMILTON,
Marbleton, Eastern Townships.

OSAGE ORANGE:—A "Subscriber" sends a sprig of a shrub grown by him from seed, and wishes to know the name of the plant. It is the Osage Orange, used as a hedge plant in the western United States, but too tender for Canada.

EDUCATION.—In reply to the enquiry of G. H., we refer him to Mr. A. Smith, V.S., Temperance Street, Toronto, who will be able to give him all necessary information respecting the Veterinary College.

LEACHED ASHES may be applied with advantage to any land, but probably with more effect on sandy soils defecient in potash. As a top dressing to meadows the effect is permanent and immediate. If used on wheat crops it has been found to cause a tendency to rust on account of the rank growth produced; but the best use to which the ashes can be applied is probably to sprinkle a thin coating over the potato sets, after dropping in the hill or furrow. In the western part of Canada there are great quantities used for this purpose.

WORMS IN HORSES.—"Bridgewater" is informed, in reference to the case he mentions, that a convenient and useful remedy for the removal of worms in horses is one ounce of oil of turpentine, mixed with four ounces of linseed oil, to be given for two mornings in succession.

TEETH A TEST OF AGE.—"Subscriber" asks, "Is it uncommon for Merino shearling ewes to have four broad teeth? or, in other words, do cases occur in which Merino (or other sheep) have four broad teeth when only one shear?" The number and development of the teeth are among the surest and most constant marks of the age of any animal, but like all other signs, are liable to variation. Some animals grow faster and mature much earlier than the average of the same species, and all writers on the subject refer to exceptional instances in regard to the appearance of the teeth. Randall says, "There is sometimes a variation of a number of months or even a year in the development of the teeth. High kept and rapidly grown sheep acquire their second teeth much earlier."

The Canada Farmer.

TORONTO, CANADA, NOV. 15, 1870.

The Harvest of 1870.

The crop reports for the present year of the districts through which the Grand Trunk railway passes have, as usual, been published, and although these accounts cannot be taken as complete, or positively accurate, yet they furnish data from which to judge of the character of the harvest in those districts, and give at least the general impression of farmers in the respective neighbourhoods in regard to the crops. It is very desirable that some reliable information on this important subject could be annually obtained and given to the public. The threshing machine is, after all, the best test of the actual yield of grain, and perhaps, the most feasible plan of collecting accurate statistics respecting the yield of cereal products would be to obtain from each man who owns a threshing machine a return of the average production of the locality in which he has carried on his operations during the season. A pretty close estimate could thus be gathered very soon after harvesting was over, not, indeed, of the total amount of grain raised, which could only be known at the end of the season, when threshing was completed, but of the average amount in proportion to the acreage sown. Such a return would often be very wide of the calculations made, in the usual manner, from the appearance of the standing crops, or the bulk of the straw. In the absence, however, of more certain means of forming a judgment, we must be thankful for such aids as are furnished by the reports which the railway companies are able to give.

These returns are, on the whole, somewhat less bright than we anticipated at an earlier period of the year, and seem to show a considerable falling off, at least in the staple grain. The report is divided into three sections, referring to the several portions of the line of railway, namely, the Goderich district, extending from Goderich to Fort Erie; the Western District, from Detroit to Toronto; and the Central (which so far as Ontario is concerned may be called the Eastern District), from Toronto to Montreal. The annexed table gives a summary of the reports from the various stations, showing what crops are reported in each as having been average, or under, or over the average yield:—

GODERICH DISTRICT.

	Average.	Under Average.	Over Average.
Wheat, Fall	3	12	0
" Spring	3	12	0
Barley	10	4	1
Oats	4	0	11
Peas	11	2	0
Hay	1	2	6
Roots	2	1	11
Potatoes	2	1	12

WESTERN DISTRICT.

	Average.	Under Average.	Over Average.
Wheat, Fall	17	11	0
" Spring	13	11	2
Barley	17	2	5
Oats	5	2	21
Peas	10	5	1
Hay	3	2	5
Roots	2	7	18
Potatoes	5	4	14

CENTRAL DISTRICT.

	Average.	Under Average.	Over Average.
Wheat, Fall	11	14	0
" Spring	12	22	0
Barley	19	16	1
Oats	14	10	9
Peas	18	6	3
Hay	7	20	0
Roots	7	14	9
Potatoes	12	6	12

From the above statement, it will be seen that the condition of the wheat crop has been most unfavourable in the Goderich district—a large proportion of the stations reporting the yield of both fall and spring wheat as under the average; while in the Western District the greater numbers report an average; and the Eastern stations again give a larger proportion of returns under the average. Barley is reported almost uni-

formly as an average crop, and the same may be said of peas. With nearly equal uniformity, the yield of oats is reported as having been very large. The chief exceptions to this are in the Eastern Districts, where in some cases the crop appears to have been light. In the same sections of country, also, hay has been a poor crop, while in the Western and Goderich Districts, the returns, where this crop is mentioned at all, are mostly very favourable. The Eastern country is also the only one that gives an unfavourable view of the root crops, which in other parts of the Province appear to be unusually abundant. But while the general yield of potatoes is large, the appearance of rot in some places may seriously diminish the available amount of this crop. The prevailing wet weather, in the Western country more particularly, has interfered with the curing and harvesting of hay, and much of it has been housed in a damaged condition. While rust has been somewhat complained of, the injury inflicted by insects has been much less than in former years. Indian corn, where it has been grown, has yielded an almost unprecedented return, and the experience of the past season will, no doubt, encourage the growth of this valuable crop to a greater extent than heretofore.

Altogether, though in some kinds of field, produce there has been partial failure, yet there has been a compensatory productiveness in others, and farmers have great cause for thankfulness in view of the general result of the year's operations.

Canadian Phosphate of Lime.

We learn from the *Chemical News* that at a recent meeting of the Glasgow Philosophical Society, Mr. W. R. Hutton read a very interesting paper on "Canadian Phosphate of Lime, and some other Mineral Phosphates now used in making Superphosphate of Lime." The following is a concise summary of the more salient points of the paper:

The author mentioned that many mineral compounds, having different characteristics and results when operated upon, are now used in the manufacture of artificial manures; and referred to the fact that agriculturists are annually making greater demands upon the manufacturers of phosphate of lime. He stated that, in general terms, the value of a mineral phosphate depends upon the percentage of phosphoric acid contained in it; but if there is any marked quantity of carbonate of lime present, the value of the phosphoric acid is much reduced, owing chiefly to the large quantity of sulphuric acid required to decompose the carbonate of lime before the phosphates can be reduced. The same remark holds true with reference to phosphatic minerals containing iron compounds in combination; the iron takes up its own equivalent of sulphuric acid, and as it is per-oxidised a compound is formed which is positively injurious to plant life. Fluoride of calcium is also invariably found in phosphatic minerals, and it, too, requires sulphuric acid, thus increasing the cost of superphosphate formed, while the gaseous fluorine compounds set free are a source of annoyance. No mineral phospate has been so extensively employed as coprolites, and none is so little understood and valued by agriculturists.

After referring to the origin and nature of coprolites, and the extent of the deposits in Cambridgeshire, Bedfordshire, and Suffolk, from which upwards of 200,000 tons are annually raised, the author proceeds to speak of the necessity for additional sources of mineral phosphates being resorted to, and new deposits being brought within the reach of manufacturers of manures, even if brought from other countries. He spoke of the German and Spanish phosphates as being very extensively had recourse to, although not so valuable as the English coprolites. Reference was made to a large and valuable deposit which occurs in South Carolina, and which has recently been brought into notice. Mr. Hutton mentioned that he was supplied some months since with specimens of phosphate of lime from Canada, obtained from the face of the material nearly fifteen feet in width, and presenting, so far as yet examined, an excellent supply of raw material. The samples differ very much from those phosphatic minerals which are now in use, and seem to indicate that if a sufficiency can be obtained, the Canadian mineral will be welcomed by manure manufacturers. Some of the specimens sent were distinct six-sided prismatic crystals, while the other pieces were in masses; but both crystals and masses had a vitreous lustre, the colour on some parts being green and bluish-green, and in other places red.

It is not stated from what part of Canada the specimens of phosphate of lime came that were subjected to analysis, but it is well known that the mineral is to be found in different localities, and in great purity and abundance in the counties of Leeds and Lanark, in the province of Ontario. In a physical point of view it is said that this Canadian phosphate differs from all others in being crystalline and not granular; while it differs chemically in containing more phosphate of lime and less carbonate of lime and sand. It is much to be desired that these resources of Canada should receive the attention which their importance demands, and be turned, as soon as possible, to a practical account.

SHORT-HORN SALE.—As will be seen by the announcement in our advertising columns, Col. Taylor will sell by auction some of his choice short-horn cattle, on the 22nd of the present month. The lot offered comprises the beautiful yearling bull "Proud Duke," bred by J. O. Sheldon, of Geneva, six cows, in calf to "Proud Duke," and three heifers,

Notes on the Weather.

The fall season, especially during the past month of October, has been unusually pleasant and favourable for such garden and farm operations as remain to be performed. Grapes, apples, and other later fruits have fully ripened, and ample oportunity has been afforded for securing them without a touch of frost; while field roots have been equally favoured in the season. He must be an incorrigibly procrastinating farmer who suffers himself to be caught this year, as many were last fall, by the occurrence of frost, before his potatoes and turnips are all safely gathered, and pitted or housed under cover. It is not often that a fall season so genial and prolonged as the present is experienced in Canada. The farmer has cause to add this to the many grounds for thankfulness which have "crowned the year."

The speciality of the weather, the character of which has been pretty uniform throughout the Province, has been its unusual warmth. We learn from the records of the Toronto Observatory that the average temperature of the month of October has been 50°, which is 4° 36 higher than the average for the month during the last thirty years, and 7° 71 warmer than October of 1869. The highest temperature, 68° 5, occurred on the 1st, which was also the warmest day, with a mean temperature of 60° 4. The lowest temperature was 30° 2, on the 19th, the only occasion on which the thermometer fell to the freezing point. The lowest mean temperature for any day was 38° 8 on the 26th.

The amount of rain-fall has been slightly above the average; rain having fallen on fifteen days to the extent of 2·690 in. The amount of cloudiness has closely approximated to the average. There were fifteen days clouded, eleven partially so, and five clear.

Westerly winds have prevailed, though there has been considerable variation in this respect, and the month has been marked by the occurrence of more than one violent storm, which caused serious disasters on the lakes, and some damage on land. The most severe of these was on the night of the 30th.

The most exceptional and extraordinary occurrence of the month was the earthquake, which affected a large portion of Canada, as as well as the United States, on the 20th. The aurora borealis has been frequent and brilliant. Altogether the month of October has been in many respects a remarkable one.

PROVINCIAL EXHIBITION PRIZE LIST.—We publish in another part of this issue a list of the award of prizes at the late Provincial Exhibition. The list has been carefully revised and corrected under official authority, and will be found a reliable record for future reference.

Entomology.

Entomological Gleanings.

BY W. SAUNDERS, LONDON, ONT.

With a fruit farm in the country frequently visited, and a fruit garden in town, my opportunities for observing the times and doings of insect foes and friends are sufficiently ample to satisfy the desires of the most active and enthusiastic "bug-hunter" that ever carried a net. Now a swarm of caterpillars disfigures the form and mars the beauty of a handsome tree, by consuming a considerable part of its foliage; again a host of aphides, by their constant sucking of the juices of the leaves, will cause them to shrivel, curl up, and often change colour, and the enormous rate at which these creatures increase adds much to the difficulty of their extermination; or some unwelcome "little Turk" sits down uninvited to feast on our finest fruits, and, not satisfied with appeasing its own appetite, leaves its progeny behind to complete the work of destruction; or it may be some rascally borer insidiously undermines one's fondest hopes by girdling and thus destroying trees or shrubs whose growth has cost years of toil and watching. With the desire of helping fellow fruit-growers and others to a better acquaintance with these expensive insect guests, I propose in this, and probably some subsequent papers, to record observations made from time to time as the season advances.

On the 6th of May the first foe was met. A lot of dwarf pear trees arrested attention from the backwardness of some as compared with others, the unequal way in which the leaves were expanding, and the dark colour, almost black, of some of the buds and younger leaves. No caterpillars were to be seen, but on jarring the trees down came the enemy to the ground in considerable numbers, partly falling, partly flying. It proved to be a small bug, belonging to the tree bug family, *Hemiptera*, and a species named *Phytocoris (Capsus) linearis*. I never remember having seen this creature doing damage before, so a careful examination of its work was made. Our foe "linearis" is not a "big bug;" it does not measure more than one-fifth of an inch. It is rather variable in colour, from dull dark brown to greenish brown, or sometimes dirty yellowish brown. The males are usually darker than the females. The head is yellowish, and has three narrow reddish stripes. The beak or sucker is about one-third the length of the body, and when not in use is folded under the breast. The thorax has a yellow margin and several yellowish lines running lengthwise. Behind the thorax is a yellow V-like mark, sometimes more or less imperfect, but usually sufficiently clear to help one to a ready recognition of the species. The wings are a dusky brown, and the legs of a dull, dirty yellow.

This enemy ensconces himself within the young leaves of the just opening buds, puncturing them about their base and along the edges, and extracting their juices with its beak. The result was to disfigure and sometimes entirely destroy the young leaves, causing them to blacken and shrivel up. They were also somewhat partial to the unopened buds, piercing them from the outside and sucking them nearly dry, when they also withered and blackened. Sometimes a whole branch would be thus affected, becoming first stunted, then withered, next dead. Dr. Harris, in his "Insects Injurious to Vegetation," mentiones this bug as occurring in Vermont in large numbers in 1851, attacking almost every green thing and doing a great amount of mischief throughout the summer. In our own case they disappeared in about a fortnight, but left the trees in a very dilapidated state. Press of other work prevented any remedies being used. Probably a solution of soft soap or dry unslacked lime would have lessened their numbers.

On the 10th of May I was astonished to see the young larva of the gooseberry sawfly, *Nematus ventricosus*, commencing its depredations on the freshly expanded leaves. This was nearly a month earlier than its usual time of appearing, the leaves having expanded about three weeks earlier than usual. On examining the under side of the eaves rows of white eggs were found in abundance in different stages of development. Those newly deposited were very much smaller than the others, and appeared to be but *slightly* attached to the surface, not let into a slit made in the leaf by the female, as is commonly supposed; at least I could find no traces of such an operation, although I examined them carefully with a microscope. The gooseberries were now in full bloom. In the second volume of the "Canadian Entomologist," p. 16, and also p. 48, an opinion is expressed that a cocoon of this insect found freshly made on the 29th of May was the work of larva which had wintered over. The observations made this spring do not in any way upset this idea, for the carliness of the season will account for the apparent discrepancy. They will certainly prove very troublesome this season, they are so very abundant, and now, at the last of the month, when many of the full-grown larvæ have gone into chrysalis, freshly aid eggs or larvæ just hatched may be found on almost every bush. Remedy—patience and plenty of hellebore, an ounce or two to the pailful, and shower lightly on the bushes with the watering pot.

There is a small caterpillar, a leaf-roller or case-maker, which is very troublesome. It probably passes the winter in the caterpillar state, for almost as soon as the buds begin to burst it begins its mischievous operations, and when first observed is not usually more than half grown. It is a very small thing even when full grown, being then half an inch in length, with a small shining black head and a dirty brown-coloured body, with a few small brown dots and fine hairs scattered over its surface. Its tenement consists of a dried-up, blackened leaf, portions of which are drawn together so as to make rude case, the centre part of which, where his highness resides, is lined with silk. It is very fond of going just where you do not want it. It is partial to the blossoms and newly-formed fruit. If you have a new pear or apple fruiting, with a single bunch of blossom on it, which you are anxiously watching, by-and-by you find that several of the blossoms have set, and while you are flattering yourself that they are doing well, along comes this mischief-maker, pitches his tent alongside this very spot, and drawing the young fruit together with silken threads, holds high carnival among them and frustrates your hopes. Another of its tricks is to gnaw a hole into the top of the branch from which your bunch of blossom issues, and, tunnelling it down, cause the whole thing to wither and die. Often it contents itself with damaging the leaves only, and this one does not mind so much, drawing one after another around its small inside case, until it forms quite a little belt of withered and blackened leaves.

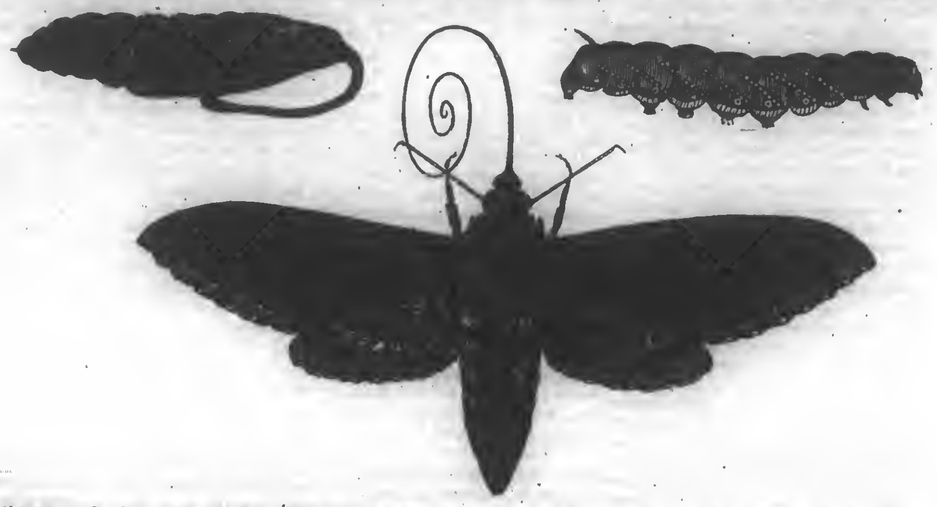
Hand picking is the only remedy suggested for these, unless you can employ small birds, such as sparrows, in hunting them up for you.

The moth which this caterpillar produces is rather a pretty little thing. Its name we are not yet able to give. It measures, when its wings are expanded, about half an inch. Its fore wings are greyish brown, with a shining white, almost silvery band across the middle, widest on the front margin. The hind wings are plain pale blue, and both are prettily fringed with fine brown hairs, those on the hind wings longest. It appears on the wing from the middle of June until the early part of July. It probably lays its eggs on the leaves, and when the young worms appear, which is most likely early in the fall, they make their small inner silken case, and, attaching themselves to some part of the tree, remain unobserved, and in this condition probably winter, awakening to new life and energy with the opening spring.

CATERPILLAR ON APPLE TREES.—Miss J. S. K., Cookstown, Ont.—We regret very much that the specimen you sent us some little time ago has disappeared without affording us an opportunity of examining it carefully. It was sent at a time when the editor of this department was in the midst of the operation of moving from his former residence to Port Hope. No doubt it escaped or was lost in the confusion and disarrangement that unavoidably take place at such times. We beg that our correspondent will accept our apologies for the mishap.

The Potato Sphinx.

Mr. James Howett, of Uxbridge, has sent us a specimen of the chrysalis of the Potato Sphinx (*S. quinquemaculata*, Haw.) which he recently found when digging potatoes. "It was about three inches under the surface in a piece of apparently solid clay, with a hole inside about twice as large as itself; another was found in a different part of the field, but was accidentally cut in two by the hoe." This chrysalis is so very remarkable in shape that it may well excite the curiosity of those who meet with it. It is about two and a half inches long by half an inch in thickness, of a chestnut-brown colour, and round in shape, tapering towards both ends; from one end, which is the head of the speci-



men, there proceeds a long curved proboscis, like the handle of a jug; the other end is divided into broad rings, and terminates in a point. The caterpillar which has turned into this creature is no less than the terrible "Tomato worm," about which one hears so many marvellous stories, and in whose supposed poisonous properties we have not the slightest faith. It is usually of a dull green colour, with yellowish-whits oblique stripes on each side of its body, and a sharp thorn-like tail; sometimes, however, its colour is bright sea-green with flesh-coloured stripes; and sometimes dark brown, or even black, with yellow stripes. It feeds upon the tomato and potato, devouring a large quantity of leaves, but seldom being numerous enough to inflict any appreciable damage upon such rank-growing vegetables. This chrysalis, if it meets with no misfortune, will turn next summer into a large handsome greyish moth, with five bright yellow spots on each side of its body; its wings expand five inches, and its body is the same length as the chrysalis; it is furnished with an enormously long tube or tongue, through which it imbibes the nectar of flowers, and which, when not in use, is coiled up into a very small compass under the head, like a watch-spring.

The accompanying illustrations represent the insect in its three stages of caterpillar, chrysalis, and moth, and will afford the reader a better idea of its appearance than any length of written description.

The Slug on Pear and Cherry Trees.

"The insect generally called the pear or cherry tree slug (*Selandria cerasi*, Peck) has in our grounds been so few and so little injurious this season that we had almost forgotten to notice it, until, passing the orchard of one of our neighbours a few days since, we saw his pear trees almost entirely denuded of their foliage by reason of the slug. It is a little singular that any cultivator can neglect to guard against such results, when merely dusting the foliage with lime, plaster, or even the ordinary dry soil, will at once destroy the insect. The first brood is now about over, but a second one may be looked for from the fifteenth to the last of August, and they should be carefully watched for and destroyed by all who wish health or vigour to their young pear or cherry trees."

The above is from a correspondent of the *Journal of Agriculture*, who writes over the signature of "Addi," and whose articles abound in common sense, and are usually very correct; but in stating that the Pear and Cherry Slug can at once be destroyed by ordinary road dust he has made a very pardonable error, and has been deluded either by hasty observation or by the unreliable testimony of others.

Though not very troublesome in the West, this insect often does much damage in the more eastern States, and it has this year absolutely stripped many orchards of every vestige of green along the line of the Michigan Central Railroad, leaving nothing but the sere and yellow leaf robbed of its parenchyma. We found that the popular remedy was sand, there being an abundance of this commodity along the lakes; but, as our friend Mr. Wm. Saunders, of London, Ontario, has abundantly demonstrated, and as we have ourselves proved, simple sand does not kill. It sticks to Mr. Slug, so that he frequently falls to the ground, and thus it appears to kill him, but he very soon manages to divest himself of his sand-covered coat. In fact, he naturally sheds this coat several times during his growth, and if the sand is applied at the proper time it proves a positive advantage to him, by stiffening his old and useless skin, and enabling him the better to crawl out of it. If it be applied a day or two before the proper time to moult has come, then, like a good philosopher, determined to make the best of the circumstances, he concludes with some reluctance to let the soiled habit go before it is quite worn out. Common road dust is equally harmless, and even plaster will prove ineffectual, unless applied before the last moult takes place, for after this moult the slug bids adieu to his slimy coat,

Moral—Never use sand or road dust for the Cherry Slug, but rely on lime, which will burn through the skin to the flesh, or on white hellebore water, which will poison.—*American Entomologist and Botanist.*

The Dutch Doctor's Insect Remedy.

Fifteen years ago, at a horticultural meeting, when the curculio question came up, I asserted in broken English that the curculio was a tevel (a plum divel,) and will eat fruit. First the plum, then the apricot, nectarine, peach, and the apple, and I will add that since then I have observed that they work on the pear and cherry. My recommendation as a remedy was then, and is now, the German Sparling or Spatz, a small bird that builds its nest on houses, barns, and in willow trees, near the road sides. Often and again I have spoken about the importation of these birds; but my advice was not heeded. If I was a female preacher, a travelling temperance medium or an office seeker, my good advice would have been noticed, and we should now have less to suffer from the pest of curculios. The importation of these birds would not cost much. A good way to introduce them would be for the State Agricul. tural Society to appropriate five hundred dollars, and each county society fifty dollars, to be used for the importation of these birds. Then we could secure hundreds of them, to be set at liberty in each county of the state. Simple structures which would afford shelter, erected on poles, or nesting places could be fixed under the eaves of the barn or outbuildings; these places would be accepted by the birds.

Those birds should be given most to the German farmers at first, as I believe the birds would feel most at home where they could hear the Dutch language talked, and see more the way of German living. I am of the opinion that when American birds can hear music and song they will become better singers—observation has taught me this. Now these Sparlings are house birds, and stay only where man lives, and on that account would always be near our orchards. They are used to insect food, but will eat fruit as well. One thing must be kept in mind: these birds, used to animal food to satisfy their appetites, seek for insects in the winter in their hiding places, and eat the egg deposit found on the limbs and on the fallen leaves, and such as is hidden under bark, or glued to the limbs, and by this means prevent the great increase which would follow from permitting the insects to escape, or the eggs to hatch.

My hints, made many years ago, are, by many correct thinking men, both at the east and west, being adopted, and the birds are being introduced into several states, and many are about to continue the good work. But, my friends, do not wait or stop after you have read these lines, but go to work at once, immediately give this article a spread all over our happy large country, for every paper may copy this, and thereby become a public benefactor. Talk to benevolent men, to all your societies, particularly to all horticultural and agricultural lecturers who speak at fairs. Collect money this fall and send a good man to Germany to get a large number of these good, God-blessed birds. During the summer they hatch every few weeks, five young at a time; and in a short time would become so increased as to give our children good sound fruit and a plenty of it.

My word for it, if you do not import these birds, the curculio, the caterpillar, the bark louse and other insects will so increase as to destroy, not only your fruits but your nurseries and your trees. Already our nurseries are full of insects, and if not checked, in a few years more it will be hard to find a sound tree in the great west.

All our curculio catchers and remedies are of no great benefit, if my neighbours use all these destroyers and I lie on my back and do nothing; as in that case I should raise the insects, and they might catch until doomsday, and I and others who do nothing would keep them supplied. To make a law to force me to destroy my insects would be oppressive, and will never be done. But my birds may be your birds, the country's birds, the protectors and angels over all our fruits. Will you hear more? From your friend,

DR. H. SHRODER.

Bloomington, Ill.

It is, we think, a conceded point that a man who originates an idea is best qualified to carry out and perfect it. Hence we hope Dr. Shroder will introduce his favourite birds, watch them carefully, and report the first one he detects catching a plum curculio. —*Prairie Farmer.*

Entomolgical Queries and Replies.

Insect Specimens.—The insect enclosed in a letter sent by a subscriber from Esqueseing was not to be found when the letter reached us. All such specimens for identification should be sent in a pasteboard box or some such receptacle, and not loose in a letter.

Walking-Stick Insect—J. Wyllie, Ayr, Ont.—The curious insect you sent us, resembling a thin stick with slender legs, is a specimen of the Walking-stick Insect (*Diapheromera femorata*). We have received quite a number of these creatures this year, and have already given several notices of them in our columns.

Pea-weevil (*Bruchus pisi*, Linn.)—An enquirer in Toronto has sent us some peas hollowed out by an insect, and desires to know "what the insect is, and how it got there." The creature is the notorious Pea-weevil (*Bruchus pisi*, Linn.) It got into the pea by the simple process of eating into it when it was a tiny newly-hatched grub, and when the pea was young and tender. It made a very minute hole in order to get in, which very soon closed with the growth of the pea, and kept the worm snugly enclosed and hidden from view. Here it grew with the growth of the plant, eating away the mealy part of the pea, until at length it assumed a pupa state, and finally, when the pea was ripe, turned into a beetle, as in the specimens before us. In this state it would remain all winter if left undisturbed, and next spring would set about its work of propagating its kind by laying eggs in the fresh pea-blossoms. Our correspondent will find a further account of this curious insect, and illustrations of its different stages, in the Canada Farmer for April, 1870, p. 137.

Specimens for Identification.—D. M., Mimosa, Ont.—No. 1. The larva found on a shrub in a marsh, with a large number of parasitic cocoons attached to it, is a Sphynx caterpillar, not the larva of an Emperor Moth. Being dead, we cannot determine its exact species. We have never before seen a larva with so enormous a number of cocoons attached to it, though there are generally a surprising number for the size of their prey. No. 2 is the chrysalis of the American Vapourer Moth (*Orgyia leucostigma*, Smith and Abbott) covered with two or three hundred eggs, from which would come out next spring, if not interfered with, a corresponding number of very pretty caterpillars. They are, when full grown, over an inch long, of a bright yellow colour, with thin yellow hairs along the sides of the body. The head is bright coral red; the next segment has two long pencils of black hairs projecting forwards, and the last segment but one a single similar pencil pointing backwards; on the fourth and three following segments there are some short brush-like tufts of yellowish hairs; and on the ninth and tenth two little coral-red knobs or warts. These caterpillars feed singly on the leaves of the apple and many other trees, and sometimes they are so numerous as to occasion a considerable amount of damage. The male moth has broad ashy-grey wings, which expand about an inch and a quarter; the front pair are marked by a whitish crescent-shaped spot at the lower corner; the female is remarkable for possessing the merest rudiments of wings, and looking like anything but a moth; she always lays her eggs on the outside of her cocoon, as in the specimen you sent us. No. 3. The beautiful metallic coloured beetle that you picked off the road is a specimen of the Divaricated Buprestis (*Dicerca divaricata*, Say). Its larva is a white flattened worm, with a broad, almost square, flat head; it bores into the wood of beech, cherry, and other trees, resembling in its habits and appearance the notorious apple-tree Buprestis Borer. No. 4 is an extraordinarily shaped beetle that is quite abundant in old fungus, at the bases of trees and on decayed logs. It is called the Horned Fungus-eater (*Boletophagus cornutus*), the former name from its mode of life, the latter from its adornment with a pair of strangely-shaped horns that project over the head. It is certainly, as you say, an ugly customer, though perhaps more curious than really ugly.

Apiary.

Bee-Hives.

To the Editor.

Sir,—On perusing The Canada Farmer for October, I find some remarks on bee-hives exhibited at the late Provincial Exhibition, and I think it no more than just to make a few explanations on different points.

The wire screen in the bottom of my hive is *not* a drawer for catching the moth dirt. I have not been troubled with moth of any account. "Cleanliness and no moth-traps" is my motto. The wire screen in my hive is for keeping the bees in when the hive is ventilated, and keeping the moth out; it also allows all clippings and moth eggs to pass through, lodging on the bottom board, which can be drawn without in any way disturbing or interfering with the bees. The screen is to be drawn in the winter, and placed over the honey-boards, making perfect ventilation, all dead bees and drip can be removed from time to time from the bottom-board.

The "New Dominion" bee-hive is on a different principle from other hives now in use; it is a hollow-walled hive without the expense of double boarding. The frames form the inner wall, resting on sills, and folding back and forth. They can be removed and replaced without killing any bees. A thorough examination of the hive will satisfy the most skilful bee-keeper of this fact.

B. LOSEE.

Cobourg, Ont., November.

Note by Editor.—Our correspondent says his wire screen in the bottom of the hive is to "keep the moth out;" and also that it allows clippings (of comb?) and moth eggs to pass through, lodging on the bottom-board, which can be drawn without disturbing the bees. We fail to see that the reporter was far astray in calling this a moth-trap, or drawer for catching the moth dirt, etc. Clippings are "dirt," eggs make "moths," and the bottom-board draws out, evidently for the purpose of cleaning it of clippings and moth eggs, and may very properly be called a drawer. The principle of a hollow wall formed by the frames forming the inner wall of the hive is not new, as Mr. Losee thinks, but has been in use for many years, and is in use now in the United States by a few, though rejected as inconvenient by most bee-keepers. A hive so constructed was exhibited some four years ago at the Michigan State Fair.

If colonies are moved in the line of their flight, and *a short distance only at a time*, no loss of bees will be incurred.—*Langstroth.*

After-swarms usually build the most regular worker combs; and if they lay up sufficient stores for the winter, they generally make the best stock colonies.

Agricultural Intelligence.

Agricultural Shows in West Northumberland.

West Northumberland.

This county society held their show at Cobourg on Tuesday and Wednesday, the 18th and 19th Oct. The weather was favourable, though the severe storm of the night of the 17th doubtless prevented some from being present. The indoor departments of the show were held as usual in Victoria Hall, while the cattle and implements were shown in a field adjoining the Drill Shed.

Horses.—There was a good show in this class: mares and foals, young horses, farm teams, carriage horses, etc.; the principal exhibitors being Williams, Mulholland, Winters, Westington, Isaacs, Beatty and others. The show of Durham cattle was good, some very promising young stock being shown. Messrs. Isaacs, Wade, Westington, Defoe, and Beatty were the chief exhibitors. The show of Ayrshire cattle was also very good. The prizes in this class went to Messrs. Pratt, Newton, Wright, and Wade. The show of Devons and Galloways was small. In the former class Messrs. Mason, Lacy, and Pratt divided the spoils, and in the latter Messrs. George and William Roddick The show of Grade cattle was good, some very fine milk cows being shown. In this class most of the premiums were awarded to Cullis, McEvers, and Smith; in working oxen to Blizard, McDonald, and Winters.

There was a good display of long-woolled sheep, the flocks of Lean, Cullis, Pratt, Westington, Reynolds, Harper, Craig, and others being fully represended. There was about the usual show of fine-woolled sheep. In Merinoe the specimens shown were from the flocks of Hinman and Spears; in Southdowns, from those of Bourn and Eagleson; and in Cheviot, from those of Elliott and Carruthers. In Pigs and Poultry the show was about as usual, not very remarkable either for numbers or quality.

The display of Implements was rather larger than usual. The show of Grain was good, though scarcely as large as it was some former years. The fall and spring wheat was of very fine quality. Barley and peas were also very good; oats were hardly of as good quality as last year. The present seems to have been a favourable season for corn, as some particularly fine samples were shown. The first prize was awarded to an eight-rowed yellow, and the second to an eight-rowed white corn, the ears in both cases being remarkably long. The root department was well filled, and the quality in almost every case all that could be desired. The potatoes, turnips, carrots, mangles, etc., shown would have been hard to beat anywhere. There was a large and fine show of butter, both in kits and rolls. Two lots of Factory cheese, and several lots of home-made, all good.

The show of fruit was much smaller than usual, which is rather remarkable seeing the season has been favourable for fruit, and the crop of apples is plentiful and of fine quality in the country this year. Perhaps *every* person thought every *other* person would be there with good fruit, and concluded that he would bring none.

In Domestic manufactures and ladies' departments, the show was about as usual, the articles being all good and "too numerous to mention."

The total number of entries exceeded 1,100.

Hamilton.

The annual fall exhibition of the Township of Hamilton Agricultural Society was held at Cobourg on Tuesday, the 11th Oct. The morning was very wet, which doubtless prevented many from being present. The show of horses was on the whole good; some good mares and foals and young stock, with some fine spans of carriage horses and single buggy horses were on the ground.

In cattle, there was a good show of Durhams, Ayrshires, and Grades. No Galloways and few Devons were shown. There were upwards of a hundred head of cattle on the ground. In Sheep, the long-wools made a fine display. In the aged ewe class eleven pairs were shown, all worthy of a prize. There was about the usual number of pigs and poultry shown, of fair quality. The grain, roots, ladies' department, etc., were shown in Victoria Hall. In Grain and Roots the show was uncommonly good, the quality in some cases far surpassing that of the same articles in the late Provincial Exhibition. The dairy department was also very good. There was a considerable falling off in fruit, and also in the ladies' department. What was shown was good, but there was not so much of them as usual. The show of implements, though not extensive, was somewhat larger than usual.

Township of Haldimand.

The Haldimand Township Agricultural Society held their annual exhibition at Grafton on Wednesday, the 12th October. The forenoon of the day was very fine, but a few showers in the afternoon made the show not quite so pleasant. This society has one of the best show-grounds in the country. On the north of the village on a fine knoll, well fenced in, with the drill shed near the middle, with suitable sheep and pig pens and a horse track and ring for judging the cattle. The drill shed amply accommodates the grain, roots, ladies' department, etc., while all the stock is on the ground around. The show was on the whole good, though not quite equal to some former ones. In the Horse classes there were some good mares and foals shown, also some very promising young horses. The teams shown for farm work were very good, the carriage and buggy horses middling, and in regard to those

shown for saddle horses,—well, the less said the better.

The most noticeable feature in the Cattol department was some fine young Durham cattle, imported this season by Mr. George Isaacs of this township, from Aberdeenshire, Scotland. They promise to be a great acquisition to the live stock in this section. There was a fair show of sheep and pigs. The show of grain and roots was good, so far as it went, but there was not near the quantity of them that this township ought to, and can show, if the farmers choose. In dairy products, articles of domestic manufacture, and ladies' department, the show though not very large, was good. The show of fruit was both large and good.

The close of the show was somewhat diversified by the presentation by the members of the society of a beautiful silver inkstand and gold pen to their worthy secretary and treasurer, Josias Gillard, Esq., who for the last twenty-one years has discharged the rather onerous duties of these offices to the satisfaction of the society. A well deserved present, alike honourable to them and him.

Halton County Fair.

This fair, held at Milton Oct. 10th and 11th, proved very successful so far as entries of stock and attendance went. Fully five thousand of the yeomanry of the county, with their wives and families, were on the grounds on the 11th, the opening day of the fair. In horses the show was an improvement on former years, both in numbers and quality. There seems to be an advance towards using a heavier class of stallions, more suited to getting stock adapted to work the strong heavy soils of this county. The farmers' teams shown were fine heavy horses. Of cattle there was a fair show in Short-horns and grades, but nothing else. Some good animals were to be seen, but the decisions of the judges in awarding the prizes were evidently based upon a want of knowledge, or showed partiality, as some of the prize animals were much inferior to others that were passed over. The sheep classes were well filled, and some fine ones shown in the Leicester and Cotswold classes, though none of them can be considered full bred. They were larger than usual, and as there was a class for cross-bred sheep, many who had taken prizes, as in the other classes, showed animals in this from the same flocks, and got a double recognition of merit. The pigs were quite up to the mark, the large breeds seeming to preponderate, though in reality many of them were cross-bred. Of grain there were forty samples, and all of them first class. A good show of butter and cheese was made, but as the judges never tasted a sample, we should like to know on what principle they acted in awarding the prizes. The show of roots and vegetables was inferior, but that of fruit was large and fine.

Galt Sheep Fair.

The Galt Sheep Fair was held Oct. 14, in the grounds belonging to the Queen's Hotel, and a large crowd of people were present. About 300 sheep, of which 200 were rams and ram lambs, were brought in to the fair, but owing mainly to the lateness of the season, and it being a first attempt at inaugurating annual sales of this description, and consequently not yet known much outside of the neighbourhood, the competition for animals was mainly confined to the local buyers, there being only two or three from the United States present. The animals brought in were chiefly of the Leicester breed, with a few Southdowns, and taking them in all, we have never seen a finer lot of sheep brought together in Canada. The auctioneer commenced at 1 p.m. with a lot of Leicester ram lambs from the flock of Peter Marshall, South Dumfries. These went off briskly at from $10 to $30 each. Some ewes sold at $12 to $20 per pair. Several lots from other breeders went for low prices, till those of Alex. McPhail, North Dumfries, came in. They brought fair prices—averaging about $12 each for ram lambs, and $14 to $20 per pair for ewes. Next came a splendid lot of pure-bred and very fine Leicesters, from the flock of James Cowan, of Waterloo. A few of these were sold at prices ranging from $10 to $40 each. The best being withdrawn, and the time for the train to leave having arrived, we left at 3 p.m., without waiting for any further results of sales, although there were still a large number to be sold. It is intended to have this fair some weeks earlier in future, when a larger attendance of American buyers may be expected, as they prefer using rams at a much earlier date than our breeders are accustomed to.

The *New Zealand Gazette*, published on Wednesday, July 13, states that the total number of acres under crop in 1870 was 900,504, as against 687,015 in 1869, thus showing an increase of 213,489.

The Smithfield quarterly cattle fair, held on the 10th inst., was well attended and animated. Buyers snapped at all cattle any way approaching beef: prices ranged from five to six dollars per 100 pounds.

The Alameda Beet Sugar Company, in California, has from 300 to 400 acres in beets. The machinery for the factory cost $120,000—the factory $20,000. The superintendent is A. D. Bonesteel, lately of the factory at Fond du Lac, Wis.

The owner of a threshing machine, who has done a good deal of thrashing for several years past, informs the Guelph *Advertiser* that the wheat this year yields on the average about fifteen bushels to the acre; the sample though better on the whole than last year, is not first-class, such as produced in former years.

Stringent measures have been taken to guard against the introduction of rinderpest from the Continent into Great Britain. Among other preventive measures, all cattle from the Continent are to be slaughtered immediately on their arrival at any English port.

The last monthly report of the United States Department of Agriculture states that the corn has been injured in some localities, but not enough to threaten a material reduction of the anticipated aggregate. There are complaints in regard to the cotton crop, but the general prospect is not discoursging.

The French Agricultural Societies have put off all their meetings, as the whole force of the country is required for its defence. The Paris Society of Carpenters has decided that the sum of 1000fr., destined for its annual *fete*, shall be applied in aid of the families of agricultural labourers of the neighbourhood serving in the army. It is the same all over the country.

Albion Agricultural Society.—The fall show of this society, held in the village of Bolton, on the 13th of October, was the most successful exhibition yet held under their auspices. Both in the number of entries and in the quality of the stock, as well as in the general excellence of other departments, there was a marked improvement over former exhibitions.

Foot and Mouth Disease.—We have again, says the *Veterinarian*, to report an increase in the spread of the foot and mouth disease. The malady prevails in forty-five counties of England and Wales, and ten in Scotland. The largest number of infected places are reported from Cheshire, Cumberland, Dorsetshire, Lancashire, Somersetshire, Staffordshire, and Yorkshire; the total number of centres of infection being nearly 4000. In Ireland also the disease is spreading, more especially in those districts where opposition is offered to the enforcement of the provisions of the law.

Sale of Shorthorns.—On Tuesday, Oct. 25th, an auction sale of shorthorn cattle took place on the farm of Mr. William Thomson, Markham township. The list of animals sold was made up by drafts from Mr. Thomson's own herd, to which some from those of J. S. Thomson, Whithy, and Robert and William Miller, Pickering, were added. The stock was in fine condition and sold well. Eight bull calves were offered, of which five were sold, bringing $520, or an average of $104 each. Fourteen cows and heifers were offered, and all sold, the sum realized being $2608, or an average of about $185 each. The best prices realized were $305 for "Lizzie," a light roan, from Camellia by Prince Alfred [553]; $280 for a five-months old red heifer "Oxford Maid," by Highland Chief from Mayflower; $250 for "Loretta," by Ashdale [30] from Blossom, a handsome dark roan three-year old. Hon. George Brown was the largest purchaser.

Award of Prizes at the Provincial Exhibition, 1870.

HORSES.

CLASS 1—BLOOD HORSES—26 ENTRIES.

JUDGES—George Anderson, Rednorsville; John Peters, London; and Wm. Carrick, Oban

Best thorough-bred stallion, four years old and upwards, Dr. Morton, Bradford; "Extra," imported 1870 ..... $106
2nd do, Charles Payne, Reach, "Jack the Barber" 26
Best 2 years old stallion, James Lawrence, Bradford 15
Best yearling colt, John Shedden, Toronto 10
2nd do, Nelson Yates, Scarboro', "Bill Fagan" 7
Best thorough-bred stallion of any age, Dr. Morton, Bradford, "Extra" ..... Diploma
Best mare, and foal, or satisfactory evidence that a foal has been raised this season, John Shedden, Toronto, "Julia Adams" 21
2nd do, Geo. D. Morton, Bradford, "Rose of Allandale" 14
3rd do. Nelson Yates, Scarboro', "Rosebud" 7

NOTE BY JUDGES—We regret to remark that the animals in this class were badly represented in numbers, but that the few exhibited were of superior quality.

CLASS 2—ROAD OR CARRIAGE HORSES—219 ENTRIES.

JUDGES—James Silver, Queensville; Charles Rowe, Prescott; J. H. Crawford, Drummondville; and Charles Girvin, Nile.

Best roadster or carriage stallion, 4 years old and upwards, E. W. Pitt, Georgetown $36
2nd do, Robert Thorburn, Gwelda 26
3rd do., Tench and Ellis, Drummondville 16
Best do., 3 years old, M. Keenan, Oneida 21
2nd do., Simon Beattie, Markham 14
3rd do., J. S. Lawson, Gore of Toronto 7
Best do., 2 years old, George Richardson, Vaughan 15
2nd do., James Goode, Reach 10
3rd do., James Barbour, Vaughan 5
Best yearling colt, Simon Shunk, Vaughan 10

3rd do, J. & R. Hunter, Pilkington, "Dominion Belle" 10
Best two years old heifer, J. S. Thomson, Whitby, "Minnie Annandale," imported 1870 32
2nd do, John Snell, Edmonton, "Rosamond" .. 12
3rd do F. W. Stone, Guelph, "Cambridge 10th" 9
Best one year old heifer, J. S. Thomson, Whitby, "Red Rose," imported 1870 24
2nd do, J. S. Thomson, Whitby, "Loretto" .. 9
3rd do, John M. Bell, Pickering, "Empress" .. 6
Best heifer calf under one year, J. & R. Hunter, Pilkington, "Princess" 10
2nd do, John Snell, Edmonton, "Rosa Bonheur" 6
3rd do, John M. Bell, Pickering, "Lady Belle" 4
Best herd of Durham Cattle, consisting of one bull and five females of any ages, John Miller, Brongham 30

NOTE BY JUDGES.—We, the undersigned Judges on Durham cattle, cannot refrain from expressing the gratification we experienced at the high standard of excellence and general good qualities of the animals exhibited we being of opinion that they were superior, taken as a whole, to what we have seen at any former Exhibition.

CLASS 6—DEVONS—71 ENTRIES.

Judges—Edward Jones, Stamford; Thos. Donald, Mandemin; and Jacob Young, York.

Best bull, 4 years old and upwards, Geo. Rudd, Puslinch, "Wilmot" $30
2nd do, John Moore, Etobicoke, "Duke of Dorset" 20
3rd do., Peter Rowe, Collingwood, "Havelock" 10
Best 3 years old bull, Richard Foley, Darlington, "Heartland" 30
2nd do., W. and L. Courtice, Darlington, "General Grant" 20
3rd do., Nathan Choate, Hope, "Prince Arthur" 10
Best two years old bull, E. C. McCollum, Campbell's Cross, "Captain Jinks" 24
2nd do., R. D. Foley, Darlington, "Theodore" 16
Best bull calf, (under one year) Richard Foley, Darlington, "Sir Gilbert" 15
2nd do., Nathan Choate, Hope, "Splendor" .. 10
3rd do., do. do. "Bruce" 6
Best bull of any age, Richard Foley, Darlington, "Heartland" ..... Diploma
Best cow, Geo. G. Mann, Bowmanville, "Lady Bird" 20
2nd do., Geo. Rudd, Puslinch, "Lady Ann" .. 15
3rd do., W. and L. Courtice, Darlington, "Queen of Cleverdon" 10
Best 3 years old cow, Geo. G. Mann, Bowmanville, "Tulip" 20
2nd do., H. H. Spencer, Whitby, "Princess" 15
3rd do., Thos. Guy, Oshawa, "Helena" 16
Best 2 years old heifer, Geo. Rudd, Puslinch, "Crimrose" 10
2nd do., H. H. Spencer, Whitby, "Rose" 12
3rd do., Nathan Choate, Hope, "Maud" 8
Best one year old heifer, Geo. G. Mann, Bowmanville, "Princess Royal" 12
2nd do., Richard Foley, Darlington, "Fairy Belle" 9
3rd do., Geo. Rudd, Puslinch, "Lady Pink" ... 6
Best heifer calf (under one year), Richard Foley, Darlington, "Bell" 10
2nd do., W. and L. Courtice, Darlington, "Ida May 2nd" 6
3rd do., Geo. Rudd, Puslinch, "Dairy Maid" .. 4
Best herd of Devons, consisting of one bull and five females of any age or ages, N. Choate, Hope 20

CLASS 7—HEREFORDS—27 ENTRIES.

JUDGES—Sandford Howard, Lansing Mich.; Joseph Garner, Pelham; and James Laidlaw, Guelph.

Best 3 years old bull, F. W. Stone, Guelph, "Sir Charles" $30
Best 2 years old bull, F. W. Stone, Guelph, "Commander-in-Chief" 24
Best bull calf (under one year), George Hood, Guph, "Robin Hood 2nd" 15
2nd do. F. W. Stone, Guelph, "The Guelph Baronet" 10
3rd do. do. do. "The Wellington Chief," 5
Best Hereford bull, any age, F. W. Stone, Guelph, "Sir Charles." ..... Diploma.
Best Cow, F. W. Stone, Guelph, "Vesta 2nd," Imported; previously exhibited 40
2nd do. do. do. "Graceful 2nd" .. 15
3rd do. do. do. "Bonny Lass" 10
Best 3 years old cow, F. W. Stone, Guelph, "Vesta 4th" 20
Best 2 years old heifer, F. W. Stone, Guelph, "Graceful 4th" 16
Best one year old heifer, F. W. Stone, "Baroness 7th" 12
Best heifer calf, (under one year), F. W. Stone, Guelph, "Graceful 5th" 10

Best herd of Hereford cattle, consisting of one bull and five females, of any age, or ages, F. W. Stone, Guelph 20

NOTE BY JUDGES—The Judges consider the entire class of Herefords of superior excellence, and worthy of special commendation. They would also remark that the bull "Sir Charles" is an animal of great merit, combining large size with fine symmetry and first-rate quality. The animals brought to our notice were, in many instances, so nearly equal in merit, that it was by no means easy to discriminate between them.

CLASS 8—AYRSHIRES—127 ENTRIES.

JUDGES—Wm. Young, Carlow; John Adams, Edwardsburgh; W. Hay, Maryboro', and Donald Fraser, Odessa.

Best bull, 4 years old and upwards, Jas. Laurie, Scarboro', "Avondale," $30
Best 3 years old bull, Thomas Guy, Oshawa, "Lion," 30
2nd do. J. P. Wheeler, Scarboro', "Prince Albert," 20
3rd do, W. H. Wallbridge, Belleville, "Dominion," 10

DOMESTIC WINES

Professional and Commercial List.

Best half-dozen dry wines James Brown, Toronto $12
2nd da, Samuel Conover, Toronto Township.. 8
Best half-dozen sweet wine, V. Casci, Toronto. 7
2nd do, James Brown, Toronto 5

NOTE BY THE JUDGES.—The Judges are decidedly of opinion that the number of Pears in section 7 should be limited. One exhibitor shows 15 varieties another 75, which is confusing We think it would be much better to word the next list thus:- Best 15 varieties Pears, 3 of each; and if it is thought advisable to offer a prize for a larger number, let it be definite - say 30, 40 or 50 varieties.

CLASS 31—FRUIT—314 ENTRIES.

General List. Professional Nurserymen excluded

EXTRAS—D. S. McFarlane, Pickering, home made plaid, $1; Alex. McLaren, Caledon, flannel shirt, $1; S. T. Willet, Chambly, piece of tweed flannel, $3; Edward Law, Kingston, sash cord, $1.

OMISSION.—Mr. Charles Boeck, of Toronto, received a diploma for an assortment of brushes at the Exhibition, as well as a first prize.

NOTE BY THE JUDGES.—The Judges recommend that in future the coloured fancy flannels be entered separate from white and plain colours.

The custom of renting rams for a year instead of selling them is quite common among English sheep breeders. Recently one gentleman let 120, at an average price not far from $50 gold each. The highest price was about $200 gold. These were Lincoln sheep; at another letting one ram was let for about $250 gold.

Miscellaneous.

The Grain Exchange of the World.

No two syllables are more familiar in every grain-growing country of the four continents than Mark Lane. They head a column of all British newspapers; are quoted in French, German, Spanish and American journals. The corn exchange takes the name of the street in which it stands. It is the only market in London for corn, grain and seed. England is always a buyer of grain. The 77,000,000 acres in the United Kingdom never produce a sufficiency of cereals in the most abundant harvest to fill the mouths of the 32,000,000 people through the year. Hence the price that England pays for grain, settled tri-weekly at the corn exchange in Mark Lane, rules the prices not only at home, but slightly decreasing in the ratio of distance, all over the world. Mark Lane stands in the heart of mercantile London. It is close upon the Thames. On every side are vast warehouses, crammed with the freights borne in by every tide. Pendulous bales swing from fifty feet aloft. Casks plunge and duck headlong into collars. The street is jammed with loaded wains. The wayfarer dives beneath nosebags, and rubs shoulders with dripping tires of broad-wheeled wagons.

The Corn Exchange stands in the centre of Mark Lane, on the eastern side. It was built soon after 1747, when the present system of factorage commenced. In an open Doric colonnade, sheltered, well lighted, roofed in from the weather, and covered by a large and handsome dome, stand before stalls filled with samples of every variety of grain and pulse productive of food for man and beast, factors and millers, lightermen and granary-keepers, bluff country gentlemen and Kentish farmers. There are more than seven hundred independent places of business. The counters are polished by the friction of grain. They are covered with open canvas bags, containing samples. All responsibility rests with the principals; who, if they do not deliver goods according to the sample, must abide the disagreeable consequences. Grain lies in heaps everywhere. It is under the stalls, on the seats, over the counters, and ankle deep covering the floor. The ever moving crowd are grinding it under foot. A hundred hands are taking samples from the bags, rubbing and comparing and "palming" them, and then throwing them upon the floor. "Why is not the grain returned to the bag?" was the question put to a friend. "That would never answer," he replied. "Suppose I were buying oats. I take a sample; try its dampness or dryness in my hand; shift it to my other, move it about, and examine its colour, smell, and taste. It has lost its dryness or dampness, is no longer a sample; and to return it to the bag would be to deceive the next comer. Of course I throw it on the floor. It is somebody's perquisite."—*The Independent.*

The Wool Product of the World.

We have before us an enquiry from a patron of the *Western Rural*, as to which is the heaviest wool-producing country in the world, and will answer by giving the following estimates of German statisticians, presuming them relatively correct:—

	Pounds.
Great Britain	260,000,000
Germany	200,000,000
France	123,000,000
Spain, Italy and Portugal	119,000,000
European Russia	125,000,000
Australia, South America, and South Africa	157,000,000
British North America	12,000,000
United States	95,000,000
North Africa	49,000,000
Asia, very general estimate	470,000,000

The aggregate production of the wools of the globe, by these estimates, is 1,610,000,000, or a pound and a quarter to each inhabitant, reckoned at 1,285,000,000 people.—*Ex.*

Two men in Boston have invented a device by which a horse is unhitched at once from a vehicle of any sort. A touch of the foot upon a treadle near the dash board releases the animal with a certainty, and applies a break which stops the carriage within a rod

The California State Board of Agriculture have awarded State premiums to Mrs. E. M. Weston, Sacramento, for 626,000 silk cocoons; A. Packard, of Santa Barbara, for 150,000 cocoons: H. G. Ballow, of Yolo county, for 100,000 cocoons; and to several parties for mulberry plantations.

As an evidence of the extent of the cattle trade around Elora, the *Times* states that during the past week there was shipped from the Elora station nineteen car loads of cattle, each car would contain on an average twenty-one head, or a total of say four hundred head. In addition to this, several droves were driven to Guelph.

EXTRACTING WHEEL GREASE, ETC.—I have cleaned wheel grease from a nice silk thus: Laying the silk on a clean sheet folded to eight thicknesses, I rubbed the greased part with a soft cloth dipped in lard, moving the silk to a new spot frequently. After a time the wheel grease all went through, leaving only clean lard. This was then cleaned out in the same way, by rubbing it with some nice soap and alcohol, using a clean cloth to rub with, and frequently changing to a new spot on the under-laying sheet. The silk was then laid on a clean cloth, and rubbed dry with a soft cloth. A friend cleaned white Canton crape in this way, and you cannot find a place where it was greased.

DENOMINATIONAL OXEN.—A gentleman travelling in Texas met on the road a waggon drawn by four oxen, driven by a countryman, who, in addition to the skilful flourish and crack of whip, was vociferously encouraging his horned horses after this fashion:—"Haw, Presbyterian! Gee, Baptist! Ahoh, Episcopalian! Geet up, Methodist!" The traveller stopped the driver, remarking to him that he had strange names for his oxen; he would like to know why he thus called them. Said the driver: "I call this ox Presbyterian, because he is true blue and never fails, pulls through difficulties, and holds out to the end; besides, he knows more than the rest. I call this Baptist, because he is always after water, and seems as though he'd never drink enough; then, again, he won't eat with the others. I call this Episcopalian, because he has a mighty way of holding his head up, and if the yoke gets a little tight he tries to kick clear of the traces. I call this ox Methodist, because he puffs and blows and bellows as he goes along, and you'd think he was pulling all creation, but he don't pull a pound unless you continually stir him up."

The Country Gentleman
FOR 1871.

"The Best of all Agricultural Weeklies in America," says *The Horticulturist, New York.*

"It has No Equal in the Entire Field of American Agricultural Journalism."—*Maine Farmer.*

THE CULTIVATOR & COUNTRY GENTLEMAN has been much enlarged and improved during the past year, and continues to maintain its former rank as the STANDARD JOURNAL OF AMERICAN AGRICULTURE. Including all the departments connected with the Cultivation of the Soil for profit or pleasure, it is its aim to promote the best interests of its readers,—to protect them from fraud and falsehood,—to provide them with the information most essential in their calling,—and, leaving to others the task of furnishing the transitory entertainment of the hour, to present a periodical of frequent issue, always fresh and seasonable, and *especially adapted* in every department to the practical wants of the FARMER and his FAMILY.

In Extent of Correspondence—
In Practical Suggestions—
In Agricultural News—

it is believed to be WITHOUT AN EQUAL, and it should be placed in the hands of every Farmer, Fruit-grower, and Breeder in the country. For them, as well as for their wives and children, the interest and value of its contents have never before been so great as now.

TERMS.—The terms are lower than those of *any other paper* of similar standing: One copy, $2.50 per year; Four copies, $9; Eight copies, $16.

☞ *All* NEW *Subscribers to* THE CULTIVATOR & COUNTRY GENTLEMAN *for* 1871, *paying in advance previous to the close of* 1870, WILL RECEIVE THE PAPER WEEKLY, *from receipt of remittance to January* 1*st*, 1871, WITHOUT CHARGE.

☞ *Any person wishing to try the paper before subscribing will be supplied with copies regularly from date of application to Jan.* 1*st*, 1871, *for the nominal price of* 25 *cents, or* TEN COPIES, *if applied for at same time, for* ONE DOLLAR.

BREAKFAST.

EPPS'S COCOA.

GRATEFUL AND COMFORTING.

THE very agreeable character of this preparation has rendered it a general favourite. The *Civil Service Gazette* remarks:—"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected cocoa, Mr. Epps has provided our breakfast tables with a delicately flavoured beverage which may save us many heavy doctors' bills." Made simply with boiling water or milk. Sold only in tin-lined packets, labelled—

PUBLIC SALE
OF
SHORT-HORN CATTLE
Berkshire Swine
AND OTHER STOCK.

I WILL sell on **WEDNESDAY, the 23rd day of November next,** at my Farm near Tallula, Ill., on the Jacksonville Division of the Chicago & Alton R. R., my herd of Short-Horn Cattle, consisting of ten head No. 1 Bulls, including the Prize Bulls Duke of Forest Hill., Major Story and Major Jones, (the latter has never been beaten in the show ring; has taken six first prizes this fall;) sixteen Cows and Heifers, including all my prize animals. I can safely say that it is the opinion of many of the best judges that this herd of Cows is second to no herd in the country. Nothing would have induced me to part with this stock, but the state of my health being such that I cannot hope to be able to give it the necessary attention.

I will also sell 50 head of Pure Bred Berkshire Swine. Some fine South Down Sheep.
20 head of First-Class Jacks and Jennetts.
Some fine Mules and Horses.

I want it distinctly understood that every animal offered will be sold to the highest bidder; there will be no reserves or by-bidders. Terms made known on day of sale. Tallula is 21 miles from Jacksonville and 68 from Bloomington. Parties attending the sale will be provided for on the arrival of trains, either day or night.

NEW ARRANGEMENTS AND GREAT INDUCEMENTS.

Wishing to give more attention to the raising of bees and queens, I offer the following inducements till the close of the coming Provincial Fair:—

To any person sending $3, I will send my single-boarded hive with improved entrance, price $3, or an individual right, price $3, and my dollar book on bee culture, soon to be published; tickets will be sent for the book. For $5, both hive and right, or an Italian queen, and the book. For $10, or the highest bid above that, during the next six weeks, a township right and the book. For $12, or highest bid above that, a township right, one hive, and the book. For $400, or highest bid above that, a right for the entire Province of Quebec, with the exception of two or three counties that are sold; this right is worth $2,000. For $200, or highest bid above that, I will sell a patent for a Self-oiling Buggy Hub, lately introduced; specimen carriage to be seen at Brooklin, Ont.; this patent is worth $2,000. Sale of townships not to interfere with sale of hives upon the above conditions.

J. H. THOMAS,

DOMINION OF CANADA

V. R.

EMIGRATION

TO THE

PROVINCE OF ONTARIO.

To Capitalists,
Tenant Farmers,
Agricultural Labourers,
Mechanics,
DAY LABOURERS,

And all Parties desirous of Improving their Circumstances by Emigrating to a New Country.

THE attention of intending Emigrants is invited to the great advantages presented by the Province of Ontario. Persons living on the interest of their money can easily get eight per cent. on first-class security.

Tenant Farmers with Limited Capital

Can buy and stock a Freehold Estate with the money needed to carry on a small farm in Britain. Good cleared land, with a dwelling and good barn and out-houses upon it, can be purchased in desirable localities at from £4 to £10 Stg. per acre. Farm hands can readily obtain work at good wages. Among the inducements offered to intending Emigrants by the Government, is

A FREE GRANT OF LAND

(WITHOUT ANY CHARGE WHATEVER.)

Every Head of a family can obtain, on condition of settlement, a FREE GRANT of two hundred acres of land for himself, and one hundred acres additional for each member of his family, male or female, over eighteen years of age.

All Persons over 18 years of age can obtain a FREE GRANT OF 100 ACRES.

The Free Grants are protected by a Homestead Exemption Act, and are not liable to seizure for any debt incurred before the issue of the patent, or for twenty years after its issue. They are within easy access of the front settlements, and are supplied with regular postal communication.

Registers of the Labour Market

And of Improved Farms for sale, are kept at the Immigration Agencies in the Province, and arrangements are made for directing emigrants to those points where employment can be most readily obtained. Several new lines of railway and other public works are in course of construction, or about being commenced, which will afford employment to an almost unlimited number of labourers.

Persons desiring fuller information concerning the Province of Ontario, are invited to apply personally, or by letter, to the Canadian Government Emigration Agents in Europe, viz: Wm. Dixon, 11 Adam Street, Adelphi, London, W. C.; J. G. Moylan, Dublin; Charles Foy, Belfast; David Shaw, Glasgow; and E. Simays, Continental Agent at Antwerp.

Also to the Emigration Agents in Canada, viz:

John A. Donaldson, Toronto; R. H. Rae, Hamilton; Wm. J. Wills, Ottawa; Jas. Macpherson, Kingston; L. Stafford, Quebec; J. J. Daley, Montreal; R. Clay, Halifax, Nova Scotia; Robert Shives, St. John, and J. G. G. Layton, Miramichi, New Brunswick, from whom pamphlets issued under the authority of the Government of Ontario, containing full particulars in relation to the character and resources of, and the cost of living, wages, &c., in the Province, can be obtained.

JOHN CARLING,
Commissioner of Agriculture and Public Works for the Province of Ontario.

Department of Immigration,
Toronto, October, 1869. v2-2-12t.

Markets.

Toronto Markets.

"CANADA FARMER" Office, Nov. 14th, 1870.

FLOUR AND MEAL.

The produce market generally has been dull during the past few weeks. Exportation from the leading grain centres of the West, in view of the approach of winter and the closing of navigation, has been very active. Hence all the distributing points are over-loaded with supplies. Millers in Ontario have procured wheat from the Western States cheaper than they could buy in the Province. This has of course tended to keep down prices here.

Flour—Fancy, $5.40 to $5.50; Spring Extra, $5.30.
Oatmeal—$5.00 to $5.25.
Cornmeal—$4.00 to $4.75.
Bran—$13.

GRAIN.

Wheat—Spring, $1.10 to $1.15; Midge Proof, $1.10 to $1.15; Scules, $1.15 to $1.25; Treadwell, $1.12 to $1.18.
Barley—Inferior, 68c.; Bright, 68c. to 72c.
Oats—42c.
Peas—66c.
Rye—70c.

HAY AND STRAW.

Hay—There has been a fair supply selling from $11.00 to $14.00.
Straw has been very scarce, and has in some instances brought as high as $13 per ton, $11 to $12 being the ordinary price.

PROVISIONS.

Beef—6c to 7c per lb.
Mutton—6c to 7c.
Pork—Mess, $25 to $26.
Bacon—12c to 13c.
Hams—14c to 16c.
Lard—12½c to 13½c.
Butter—18c to 20c.
Cheese—12c to 13c; Royal Arms, 17c; Reesor's Stilton, 18c.
Eggs—23c to 25c per dozen.
Hops—9½c to 13c.
Salt—Goderich, $1.00; American, $1.85; Liverpool, per bag, 75c.
Hogs—Live, 5½c; dressed, 6½c to 7c.

HIDES AND SKINS.

Hides—7c to 8c.
Sheepskins—40c to 80c.
Calfskins—12½c to 13c.
Wool—30c. to 31c.

New York.—*Flour*—Dull, and 5c to 10c lower; receipts, 18,000 bbls; sales, 9,000 bbls, at $4.90 to $6 for Superfine State and Western; $5.50 to $8 for common to choice extra State; $5.35 to $6.60 for common to choice extra Western. *Rye Flour*, quiet. *Wheat*, dull at 1c lower; receipts, 173,000 bush; sales, 45,000 bushels, at $1.28 to $1.37 for new No. 1 spring; $1.30 to $1.37 for winter red and amber western. *Rye*, quiet. *Corn*, dull and lower; receipts, 25,000 bush; sales, 29,000 bushels, at 89c to 90c for old mixed western. *Barley*, unchanged; receipts, 5,000 bushels. *Oats*, firmer; receipts, 34,000 bushels; sales, 29,000 bush at 56c to 57½c for western; 57c to 59c for Ohio and State. *Pork*, dull at $24.37 to $24.50. *Lard*, dull at 13½c to 14½c for steam, and 14c to 15½c for kettle rendered. *Butter*, steady. *Cheese*, quiet.

Provincial Markets.

Montreal.—*Flour*—Extra, $6 to $6 12; Fancy, $5 80 to $5 85; Welland Canal Superfine, $5 25; Superfine No. 1 Canada Wheat, $5 25 to $5 75; No. 1 Western wheat, $5 20 to $5 25; No. 2 Western wheat, $5 to $5 05; Bag Flour, $2 40 to $2 50. *Wheat*, Canada fall, $1 12; western, $1 11 to $1 12½. *Oats*—Per 32 lbs., 42c to 46c. *Barley*, per 48 lbs., 67½c to 72½c. *Butter*, dairy, 19c to 21c; storepacked, 16c to 18c. *Ashes*, pots, $6 05 to $6 10; pearls, $6 70. *Pork*, mess, $25 to $25 50. *Dressed Hogs*, $7 to $7.50.

LONDON, Nov. 8.—Spring wheat, $1.15 to $1.25. Red Fall do, 95c to $1 10; White do, $1 15 to $1 25; Barley, 45c to 52c. Peas, 62c to 66c. Oats, 35c to 36c. Corn, 65c. Rye, 55c. Butter, rolls, 19c to 21c; do, tub, 16c to 18c. Cheese, 9c to 13c. Eggs, 17c to 19c. Dressed Hogs, $6 50 to $7 12.

GALT, Nov. 8.—White wheat, $1 15 to $1 20; Treadwell, $1 12 to $1 17. Barley, 52c to 56c. Oats, 35c to 40c. Peas, 55c to 60c. Butter, 20c to 22c. Eggs, 15c to 18c. Potatoes, 25c. Pork, $6 50 to $6 75 per cwt.

Barn-yard Management.

In the course of many visits we have paid to farmers throughout the country, one of the most noticeable defects to be found, even amongst those who may be fairly considered intelligent and progressive men, is the want of any proper system of managing their barn-yards. It does not seem to occur to them that the making and saving of manure is the main point in any system of husbandry, looking forward to a steady amelioration and improvement of the productive capacity of their farms, be they large or small.

Some have their yards trodden into quagmires of mud, for want of some absorbent material; while others locate them on a hill-side, from which every rain storm washes away all the richest and best qualities of the manure into some ditch or creek. Some again do their best apparently to save all the manure they can, yet allow it to lose much of its strength and value through being dispersed over a large extent of surface in the yard.

We propose to give a few general rules to regulate management of barn-yards.

First—The yard should be so located and constructed that none of the urine or salts in the manure can be washed away.

Second—It should be entirely cleaned out, and every particle of manure be applied to the soil before the stock are to occupy it for the winter, and again commence the work of making their own food into plant food.

Third—The bottom of the yard must be made hard and solid enough to prevent the liquid elements of the manure from leaching away into the soil on which it is located.

Fourth—The entire bottom should be filled up with muck or dry loam, to act as an absorbent of the liquids; over this should be placed a layer of straw several inches in depth.

Fifth—A mixen should be formed, if possible, under a shed; to it should be carried all the droppings from the stables, byres, pigsties, etc., to be thoroughly incorporated together, and the straw and droppings of the yard mixed in as often as they can be got partially worked up by the treading of the stock. This mixen should be so managed that the manure, while being made, will ferment, yet not rapidly, so as not to become decomposed till near the time for applying it to the soil. This fermentation can be controlled by keeping the mixen moist, by adding water when too dry, and not allowing an excess of straw to get mixed into the manure.

Sixth—The entire yard, including the layer of muck or loam at the bottom, should be cleaned out and added to the mixen at least once every three months, and a fresh supply of muck or other absorbent applied to the yard and covered with straw.

By a proper course of management the amount of manure made can easily be doubled, and the yard kept sufficiently clean and dry for the comfort of the stock that are turned into it during the day time, when loosened from their stalls. It is better to keep adding fresh layers of straw, a little at a time, as the surface of the yard gets wet and dirty, than to put on a large bulk at once that will take all winter to be worked up, and then be of small value for want of composting.

To get water enough for use in the mixen, and also to wash out the floors of the stalls and byres once in a while, a cistern should be provided in the yard, to which all rain-fall on the roofs of the various buildings adjoining the yard can be conveyed by pipes, and afterwards pumped out as required to be thrown on the mixen, or used for watering the stock, if the supply is sufficient for both purposes.

This making of a mixen will cause some extra work to the farmer and his hands, but the labour bestowed upon it will be more than amply repaid in the increased value of the larger quantity and better quality of the manure manufactured by means of it. The object of having the mixen under cover is to prevent the too rapid evaporation by the sun of its best constituents, during the warm bright days of spring and early summer, before the land for root crops, to which most of the manure is usually applied, is ready to receive it. The trampling of stock on the mixen tends rather to improve it, by making it more solid and better mixed; hence it may be open to the access of stock, but they should not be allowed to lie on it.

A Backwoods Farm.

During the time that some of us were making potash, the rest were busily and constantly engaged in

LOGGING.

Here is almost the most important part of clearing a new farm. The work must go on continuously from day to day. Four rollers and one driver ought to log an acre a day, or say, unless hindered by bad weather, twenty-four acres each month. We always did this on good, dry, hard wood land, where the burn had been perfect; and subsequently, when we jobbed out five or ten acres to some hard-working young fellows, they logged nearly eight acres in one week; but, the timber was hard wood, and no brush or chip whatever, and no large elm or swamp timber predominated. Where this was not the case, and the land was wet and covered with swamp timber, and consequently the burn not so good, and often very bad, half an acre would be good work to get through in a day. Where this is the case, then the trouble begins, picking and piling, chips and brush, until it seems as if you would never get through.

The last fifty acre piece that we logged was accidentally set on fire by a neighbour, before it was half ready to burn. The fire ran through it without burning one quarter of the brush, and it required twice the time to finish the logging; in fact, it was not finished until the following season, and by that time the piece that remained unlogged was covered with Canada thistles, which seem indigenous to our land, they spring up

1954 TORONTO

everywhere, when a new fallow is left a summer unoropped; and to this day that piece feels the neglect, as the thistles are most abundant, whilst in those portions that were cropped the first year and seeded down at once, no thistles whatever have appeared.

We first tried logging with ordinary cattle, but the attempt soon convinced me of its entire uselessness. Such a job of logging as we had to do required the best team that could be had. I gave it up after a week's trial, and left the farm for parts unknown, determined not to return until I had procured a first-rate yoke of oxen,—smart, but very heavy, and not older than between seven and eight. These I succeeded in finding. They were eight years old, very heavy, each weighing at least 1,600 or 1,700 lbs., nearly 5 feet 6 inches high, and in fine condition; they girthed 7 feet 8 inches. Splendid animals they were, and we logged nearly 120 acres of land with those oxen that summer. Of course we fed them like horses, and had an accident happened, either of them would have been good beef. I have often seen those oxen break a new yoke at one jump, when attached to too heavy a log. After breaking three or four yokes I am convinced they understood the trick of doing it, and did it on purpose to be allowed the necessary rest, while we were making a new one. Our four rollers and driver, with one man to "chunk up" and burn, made short work of clearing an acre; twenty or twenty-four acres a month made a great show, and this was the result of first-class men and a crack team.

LOGGING BEES.

During the first years of our clearing up the farm, many of our neighbours made logging bees, and we were always asked, but never went. I set my face altogether against logging bees. Raising bees *may* be borne, and possibly are requisite, but bees for anything else are miserable things—a regular waste of time. For, if you get your neighbours to come to your bees, you must go to theirs, no matter how important it may be that you should not leave home; go you must. There is absolutely no saving by bee labour, at any rate. If you get fifty men to help you one day, you must go fifty days to help them, and often some one will get you to go twice, and occasionally more, to their once coming. And you may add fifty days in addition almost lost by it, as you always get racing, and are, consequently, over-worked and often strained, and seldom do anything worth while the next day after a bee but rest and recruit. We know whiskey is at the bottom of this, and any quantity of whiskey is always drunk at bees in a new neighbourhood, whilst clearing up the land. Not that this sort of labour requires whiskey more than any other, but such is the general custom. And not as long as logging bees last will the people listen to temperance doctrines. No sooner, however, is the logging all done and farming regularly begun, than farmers all at once attend temperance lectures, and they find the benefit of them you may be sure. And this is the principal cause of the great improvement in almost any neighbourhood directly the land attains the name of "Old Cleared Farms."

SPRING WHEAT.

The next year we sowed about sixty acres of spring wheat, and as the land was in first-rate order we certainly expected a first-rate crop also. All went well until the 12th of July, when the wheat was just "shot out," and on the night previous there occurred in our locality a most untimely hard frost, so much so, as to freeze water quite over, as some pieces of thin ice were found and brought into the house next morning. This is most unusual, but I distinctly recollect this frost occurred on the 12th, and that it was a holiday with some of our men who were Orangemen, and the records in the day book prove the fact as well. The effect was to prevent the grain ever filling in the upper parts of the ear, and at harvest about nine bushels an acre was the crop instead of at least thirty. Fortunately our means could stand the loss; had it been otherwise it might have ruined us. We were not one jot discouraged by this loss; wheat was high in price that year, and as expenses were about paid we were not as badly off as we might have been. Meantime our stock of cattle and colts increased.

RAISING COLTS AND CATTLE.

We had bought two or three brood mares, and a reasonably good entire horse, and we were thus enabled to breed colts without any extra expense, and nothing paid better on our farm for years than this branch. For about ten years we had only two accidents that ended fatally to the young foals. One was shot for a deer, and the other was mired in a ditch. We always worked the mare as long as we could before foaling, but not afterwards, if we could possibly avoid it. We considered that with care the mare was uninjured by such treatment *before foaling*, but that when worked afterwards the colt suffered.

The horned stock also increased fast, and now numbered over twenty-five head, all raised without any expense that could be well reckoned as such. They all increased at about the rate of $10 a year for three years, and the quality was good, as we never could bear to see the poor half-starved miserable animals such as usually are to be found about a backwoods farm. The cause of poor stock in such places is chiefly due to the miserable quality of some little runt of a bull; a wretched beast, that it would pay the settlement generally if some one of their number would shoot it, and pass round the hat to collect the value for the owner. Laws against the running of such animals at large are now generally pretty strictly observed, and in such cases the owners of the brutes are at once notified through the pound-keeper that the obnoxious animals are impounded.

GROWING BARLEY.

We held that year a great consultation as to the heavy loss arising from the failure of so much wheat two seasons following, and next year we determined to sow upwards of sixty acres of barley. Seed was very high, and we anticipated great returns, but unfortunately a remarkably dry season occurred that year, and many fields of oats and barley all over the country failed to grow more than from eight to twelve inches high. Our return at harvest was about three times our seed. Nothing daunted we determined to try fall wheat next, and therefore having well fallowed about twenty-five acres of good land the previous year, we sowed fall wheat on it and prepared about thirty acres more of fallow for spring wheat, the year following.

The weather was beautiful the next year, about April and May, and, contrary to advice, we ploughed the land twice for wheat, and got it sowed in splendid order. The dry weather continued, and our extra care did all the mischief. We soon found that the second ploughing had so loosened the soil that the wheat plant began, about the middle of June, to look miserably yellow and lean. This was to be attributed to having the soil too loose, especially when combined with dry weather. Had we had our usual June rains the soil would have settled hard and firm; but the dry weather finished what the loose soil had begun, and at harvest nine bushels an acre was our crop of spring wheat. The midge attacked the fall wheat, and we only harvested twelve bushels an acre of this.

We had seeded down a large quantity of the land this year and determined to graze cattle instead of growing wheat, until the stumps were rotten; and this year we put in only about thirty-five acres of wheat, fifteen of fall, and about twenty of spring. The fall wheat at harvest yielded thirty-five bushels to the acre, and the spring about twenty or twenty-two, and we almost regretted seeding down so much, but we nevertheless determined to seed down more, and go into cattle more extensively, and then await the rotting out of the stumps and results of draining to complete our farming operations.

BEST ROTATION FOR NEW LAND.

From all our farming experience, I am convinced that, under all circumstances, the best course to follow with new land is to get the first crop of wheat, and then seed down directly and keep the land in grass for at least seven years afterwards, or until the stumps are completely rotten and all loose. Then to collect all the small stumps, roots and rubbish, and set fire with these appliances to the large old undecayed stumps, most carefully tending the fires, never neglecting them to do other work, but steadily working amongst them all the time they are alight, constantly "chunking" up and forcing. By

this means two men can very well attend to and burn out twenty-five to thirty acres each week, provided the weather has been quite dry and the wind blows pretty fresh each day. You would hardly believe how complete a clearance can be made of hard wood stumps by this means. Last year we had a twenty-five acre field in just the right state, and one man in three days burnt almost every stump out of it. But never, under any circumstances, allow the half-and-half plan of setting a few stumps on fire whilst you are ploughing in the field. They will not be attended to or kept going, and the consequence will be that the stumps will almost all be half burned and all the dry and decayed part consumed, whilst the remainder will be quite sound and preserved by the fire from further decay for some years longer; and moreover clumps of roots trouble and annoy you for a long time.

Farming, like all branches of business, must be done right, and with capital, and to the best advantage; and if you grow grass without good stock to eat it, you suffer; and if for want of stock you grow grain when it ought not to be grown, you suffer. Many in their wisdom would say it served you right, but I know better. Farmers, until they get forehanded, must live, and must grow what their capital enables them to produce, or rather the want of it forces them to grow, and generally such farming is more the misfortune than the fault of the farmer.

C.

Beet Root and Beet Root Sugar.

No. VIII.

This subject is engaging the attention of English farmers, and from the experimental and scientific class it has passed into the hands of some of the best and most successful farmers in England, who are now growing sugar beet by hundreds of acres, and with very satisfactory results.

To show that in previous articles there has been no exaggeration respecting the produce both of the root and the sugar, the reader is requested to note the following extract from a speech made before the Chamber of Agriculture at Cirencester, in England, and which is taken from the *Agricultural Gazette*. After a lecture had been delivered on the subject by Professor Church, of the Royal Agricultural College, and the usual discussion arose, Mr. Edmund Ruck, one of the best and most successful farmers in England, stated to the following effect:

"In consequence of the several articles on the subject of beet root growing which have been going the round of the British press, he (Mr. Ruck) went to Lavenham, where Mr. Duncan, the great sugar refiner of London has erected some works for the manufacture of beet root sugar. He found there a very expensive and extensive set of buildings and machinery. Mr. Duncan had been giving the farmers of that district one pound per ton for beet, delivered at the manufactory, and the farmers took back the pulp at 13s. per ton. The crops raised ran from sixteen to twenty-four tons per acre." [I have only reckoned on ten tons per acre in Canada.] "In the third week of April last he (Mr. Ruck) went to France, with the object of examining their mode of manufacturing, and enquiring as to the profits derived from it. He found that a ton of beet would yield twenty gallons of spirit, and that the pulp would pay for the expenses of manufacture and the interest of the money employed. This spirit would sell in England at two shillings per gallon (over and above the amount of the duty), so that there is a margin of 2s. per gallon, or £2 per ton.

"In most establishments on a large scale in France, both sugar and spirit are made, and Douai is the great sugar market of France. He was surprised to find that good land was sold generally at £100 per acre in France; but if within five miles of a manufactory, then the price rose to from £135 to £140 per acre. It was not unusual to cart beet seven miles to a manufactory, and if sent by boat on canal it was sometimes taken not less than thirty miles. He found that beet had in some cases been grown for fifteen years in succession, and a yield of thirty tons per acre would give, at £1 per ton, £30 per acre to the farmer, and an equal sum to the manufacturers. His hearers must bear in mind that the pulp will pay all expenses as well as interest on the capital employed in manufacturing. There are two kinds of beet principally planted, viz., the Colet Rose, a red beet (but not the one usually planted in gardens for salad), and the White Silesian, the last named yielding the greatest per centage of sugar, but only about two-thirds the weight per acre of the former. Great attention was required not to allow their beet to grow coarse, and the only safe way to prevent this is to have the plants very thick in the ground, say in drills sixteen inches wide, with the plants cut out at eight inches apart. The three principal systems of manufacture are the Champonois, Le Plé, and the Colette. The last much resembled cider making here (in England), on a very large scale. In the Le Plé system you take out the saccharine matter (sugar) by applications of hot water. The extraction of the sugar and the spirit from the roots was too elaborate a process for him to enter into. The value of the pulp per ton varies very little in the two systems, but that from the Colette will keep any number of years, if properly stored, and the pressed pulp and "cossettes" from the Le Plé system will keep for a year or two. * * * * Mr. Ruck said that it had been proved to his satisfaction from analysis of beet grown abroad and those grown in England, that no country had a better soil or climate than England for growing them profitably. The idea that a succession of crops of beet being taken off the land is injurious to it, was in his opinion a complete delusion."

Now the foregoing evidence, coming from Mr. Ruck, cannot be too highly valued. He and his family farm most extensively and successfully; they have raised large quantities of sugar beet, and it was only a few weeks ago that they exhibited their crops of beet (among other crops) to a committee of the first agriculturists in England, who were highly gratified with them, and who in the speeches which the members of the committee made after the entertainment which followed the exhibition and examination of the Messrs. Ruck's farm, were very complimentary to those gentlemen on the results of their labours.

It will thus be seen that in the previous articles given on this subject I have carefully kept *under the mark*, and have not by any means given a flattering statement of the profits which may be relied on from the growth of beet root for sugar in Canada.

VECTIS.

Leached Ashes as a Fertilizer.

An exchange reports the remarks of Mr. Quimby at a meeting of the Rochester Farmers' Club, as follows: "Leached ashes are good for all crops—for corn in the hill, and especially valuable as top dressing for wheat and clover fields, and meadows generally. During the past three years he had drawn 10,000 bushels on his farm, which he spread on land at the rate of 200 to 300 bushels per acre. He covered forty acres in this way, and meant to ash the entire farm. They had doubled his wheat crop and wonderfully increased his crop of grasses, especially clover. Land which had been run down too much to seed with clover, produced heavy crops when manured with leached ashes. He got a good catch of clover where he applied leached ashes last year on his wheat and rye, while the balance was a failure. He could see a great difference in the growing wheat where the land was manured with ashes and where it was not."

Turnips vs. Wheat.

In one of my wanderings, a year since, during a leisure time, I chanced to receive an invitation to spend a few days with a friend to the north of Guelph, and was told that the farmers in that locality were far ahead of many other sections of the country in the growth of turnips and fatting stock. I could not at that time leave home, but this autumn, having some spare time, and also some business in that locality, I availed myself of the invitation to pay my promised visit. One great attraction was that my friend Mr. S. himself was a great lover of grade stock, and farmed 190 acres of cleared land, and grew large quantities of turnips, with which he not only fed the growing cattle, but also fattened about ten

head each year; and as he had boasted a little of his success in the culture of turnips and feeding them to stock, I thought I should derive many useful hints from him and his experience.

The stage put me down at a cross road about four miles from his house, and I soon put myself on the other side of that distance. I met with a hearty welcome, and next morning we examined the stock and turnips. There were thirty head of very handsome two and three year olds, all sired by a thoroughbred bull, and a fine dairy of sixteen cows.

The two ten-acre fields of turnips, the growth of that year, were alone well worth the trouble of inspection. There were, I was assured, at least 750 bushels per acre, and each acre was destined to feed one bullock, and afford an abundance for a proportion of the living stock beside. The plan pursued was to fallow the land the previous year, and manure in September, leaving it well ridged up and drained. Early in spring, as soon as the first crop of weeds started, the cultivator was used freely, harrowing followed, and the land was again cultivated and again harrowed as the weeds sprouted. By the twelfth of June, the seed was drilled in, and 1½ to 2 pounds an acre was sown—enough, as my friend said, for the fly and himself. The rows were twenty inches from centre to centre, and the plants were left about twelve inches apart in the rows. Their growth was most rapid by this course of cultivation, and a peculiar little cultivator or gang-plough, reversible in its action on the land, was passed at intervals between the rows. A most novel harrow was also used, made of a plank full of spikes. There was one great secret of success—never to allow the weeds to gain head. The cultivating and harrowing between the rows was soon done, but the hoeing was a more serious job.

The turnips were twice hoed *in the row*, the first time without much care except to reduce the young weeds, the second time more carefully, to thin out and single the young plants. Mr. S. told me that he should like much to take a contract to raise any quantity of Swede turnips at four pence per bushel, delivered on the field in heaps. I could not think that this would pay, but he assured me that if the turnips were consumed on the farm, the value of the manure thus made would of itself pay him a small profit towards the expense of the turnip crop.

The figures given me were as follows, premising that the fallow had to be made at any rate, whatever crop was sown, and the manure for the turnips hauled out, supposing he were going to sow spring wheat. Winter wheat had not been as certain in its results for some years past as it formerly was—not even when new land was town. He accounted for this by depreciated seed; in fact there was no other satisfactory way of doing so, and the comparison was therefore made between the turnip crop and one of spring wheat, premising, as above, that the land was prepared for either turnips or spring wheat.

The account would stand thus:—

Dr.

To seed wheat, 1½ bushels at $1	$1 50
Sowing, 25c.; harrowing, 50c	75
Once cultivating	50
Cradling and binding, with board	1 50
Hauling	75
Threshing	1 00
	$6 00
Rent of land	2 00
	$8 00

Cr.

By 15 bushels of wheat at $1	$15 00
Value of straw as feed	2 00
	$17 00

Turnip crop—Dr.

To seed, 2 lbs. at 30c	60
Twice cultivating at 50c	1 00
Twice harrowing at 50c	1 00
Drilling	1 00
Twice cultivating at 50c	1 00
Twice hoeing at $1	2 00
Digging, pitting, or hauling home, at 20c. per load	4 60
Cost of feeding covered by value of manure.	
	$11 20

Cr.

By 750 bushels turnips at 6c	$45 36

Showing a vast preponderance in favour of growing turnips at 6c., instead of spring wheat at $1, when only getting 15 bushels an acre; and this is about the average crop all over the province.

These calculations led me to enquire Mr. S.'s opinion as to the practicability of growing sugar beet at $4 a ton, or 10c. a bushel, cash, when delivered at the factory. He answered unequivocally that he would readily undertake the growth of 100 acres at that price, provided the delivery could be effected without hauling more than from one to two miles. I afterwards obtained a similar opinion from two or three practical turnip growing farmers. The chief objection made to the comparative advantages of growing sugar beet when hauled off the farms, instead of turnips consumed on the place, was the absence of the large quantity of manure made by the feeding of turnips to the cattle. One man who farms 225 acres of land informed me that he had grown as high as twenty acres of turnips a year, and fully corroborated the foregoing statement, and, as additional statistical facts, added, that all the farmers to the north of Guelph, about Elora, and still further northward, had for some years depended almost entirely on the growth of turnips and fattening cattle; but he considered it paid better to consume at least a bushel a week of chopped peas, or its equivalent in other grain, to each head of cattle fed. The manure was still better, and the cattle fed much quicker. His figures were as follows:—

To purchase of steer, four years old	$30 00
Three months' feed of grain at 1 bushel per week at 6c	7 20
200 bushels turnips at 6c	12 00
Straw *ab libitum*.	
	$49 20

His steers averaged, when fat, 1,300 lbs. each, and he obtained $5 to $5 25 per 100 pounds for them, live weight, and amounting to about $70 each, showing a good profit on the transaction, besides the manure. No hay was fed, but straw substituted. In the manure he considered himself repaid for his labour of feeding by this article alone. He assured me that he had kept separate the manure obtained from ten head of cattle, and that during the three months they were stall-fed he had hauled out thirty loads of the best manure. Of course, the cattle were liberally supplied with bedding. This was applied to a fallow where barley was grown, and the manure was carefully distributed over nearly three acres of the land. The proceeds of the three acres so sparely manured was measured and compared with the yield of the same quantity of the same field, but unmanured, and resulted in an increase of twenty-eight bushels of barley, which at 80 cents, the price obtained, made the manure absolutely worth, from these ten cattle, less the cost of hauling to the field, $22 40, or nearly $2 25 to each beast fattened.

I thought the value very low stated, as certainly the effect of the manure would be felt in several subsequent crops, and I should have been willing to place it at double the value he gave me on this account alone.

C.

Manure—Gypsum.

"Gypsum," "Sulphate of Lime," or, as it is generally known, "Plaster of Paris," is used greatly, and with usually beneficial results, by the majority of our Canadian farmers. The fertilizing powers of this manure upon certain crops and on certain soils, have been very favourably reported upon by many eminent American and British agriculturists.

The name Plaster of Paris was given when gypsum first came into general notoriety, from the fact that large beds were found and worked in the hill of Montmartre, near Paris.

The analysis of gypsum shows it to contain, of

	Parts.
Pure calcareous earth or lime, about	30 or 33
Sulphuric acid	32 " 43
Crystallized water	38 " 24
	100 100

Its dissolution in water, owing to the presence of a large proportion of sulphuric acid, is a process of slow accomplishment, requiring from 450 to 500 times its own weight of water. Its purity varies in different beds, and hence chemists have not well agreed in their respective analytical reports. A good test of its purity is obtained thus: Put the ground powder in an iron pot alone, over the fire; when it becomes heated it will give out a strong sulphureous smell, accompanied by a rapid bubbling; if this ebullition is brisk and the substance will admit of a straw being thrust with ease to the bottom, it may be considered pure.

Traces of the discovery of gypsum are discerned in the writings of the ancients; but not until the last centuries were its properties generally known in Europe. At that time some experiments of its use were reported on by eminent German agriculturists to the Economical Society of Berne, in Switzerland, when it rapidly spread over that country, France, and many other parts of Europe. It was, however, in America that its merits became most generally recognized. Indeed, it was exported to America in large quantities, and from the Delaware was conveyed as much as 150 miles by land carriage, until discovered in the State of New York.

The stone, when ground to powder, produces from 20 to 25 bushels per ton.

Experiments were made in England of the relative values of plaster simply ground and when calcined. It was thought that by burning much of the water contained might be expelled, and thus the proportionate weight be greatly reduced. The water cannot, however, be expelled from the sulphuric acid except by the most violent heat, and thus the attempt was found practically useless, and was consequently abandoned; also, experiments upon the use of plaster when calcined proved that there was an almost imperceptible difference between its effects when burned and when simply ground.

Upon our light and sandy soils the effect of gypsum seems to be most rapid and lasting, and in Canada I find that the farmers on the lighter soils apply it more generally than those on the clay lands. Upon wet land this manure has little or no effect. The growth of young clover is very materially quickened by a good top-dressing of plaster, and its benefits are more particularly observable in its application to all leguminous plants. This manure, like lime, is a stimulant. The caution contained in the last article on manures as to the evil effect of a too oft repeated application of lime, apply with more or less force to this manure also.

I have seen it used on fall wheat with various results. No doubt, it stimulates and starts a young wheat crop, but it also gives the young plant an unnatural push, which weakens its strength, and thus materially reduces its power of standing a long and severe winter. Its application in the spring on winter wheat I believe to be of great benefit. Not only does it push forward and revivify the young wheat plant after its long torpor, but it is upon the ground for the benefit of the clover crop.

Its exact means of action upon the growing plant yet remains clouded in much doubt and uncertainty. It is very generally supposed that its effect is due to its power of attaching moisture to the plant upon which it rests. Sir Humphrey Davy, however, contradicts this, for he says that even allowing gypsum to have a great attraction for water, yet the same substance, owing to the large proportion of sulphuric acid, also retains its moisture most strongly, and therefore would give it off very slowly indeed to the leaves and roots of plants with which it may be brought into contact. Moreover, this great chemist denies the fact that gypsum has a strong attraction for water, and gives the following experiment in support of such denial: ½ ounces of gypsum were exposed for three foggy nights to the air, and on the third night being weighed carefully, it was found that the increase was not quite half a grain.

It has also been urged that, when applied to clover just before rain, its effects were not perceptible. No doubt this has been owing simply to the fact that the rain has washed it off the plants into the ground, where its effects upon the plant by the root would not be so observable, because not so rapid; and yet it is well known that that part of the field upon which it has been spread invariably retains the dew for some time longer in the morning than those parts upon which gypsum has not been laid.

I think that even with these contradictory reports and opinions before us, we may, at any rate, be certain that its benefits are great upon many crops—wheat, spring grain, corn, turnips; but more especially upon clover and the grasses. For my own part, I consider that in this very power of retaining moisture consists the great value of gypsum as a top-dressing in this country.

When all other sources from which moisture may be drawn fail the plant, the gypsum is giving out its moisture, very slowly it is true, but in sufficient quantities to keep the plant supplied and growing from dew to dew and from rain to rain. In England, where they do not often suffer from a too dry atmosphere, the opinions of farmers upon the use of gypsum are very varied, and it does not seem to have anything like as proportionate a value as it has upon this our dryer continent.

At one of the regular meetings of the Ancaster Farmers' Club, last winter, when speaking to the subject of plaster, brought forward in an able essay by a gentleman of this locality, although some difference of opinion appeared to exist as to the time of application and the immediate action of this manure, yet the immense benefit to be derived from a generous use of gypsum on many crops, and more especially upon clover, was most cordially endorsed, and proved by reports of different experiments by the majority of our most successful farmers.

Ancaster. C. E. W.

Growing Green Crops for Soiling.

Some intelligent enterprising people in that part of the County of Oxford near the Township of Dereham, have for some time past been growing Indian corn, sown broadcast, for the purpose of soiling dairy stock, when the fervid heats of summer cause the grass and pasture to run short. About the middle of May they sow on the richest land they have, three bushels of corn to the acre, broadcast. The growth is so rapid and rank on rich land that no hoeing is required, and the corn soon takes the destruction of all seeds into its own hands. The stalks are allowed to attain a growth of about § of an inch in diameter, and from four to six feet high. The cattle are then plentifully supplied with them, cut and carried to their yards. They thrive wonderfully well on this food, and rather increase than decrease their milk, even when taken from good pastures, especially when the ear begins to form, at which time the cows become quite fat and the milk affords butter of the richest yellow colour. Until the ears begin to form the butter made from green corn stalks is rather white, though very sweet and palatable.

This feed is continued until fall rain has caused a fresh growth of grass. The remaining corn, that has by this time become rather old and stalky, is cut with a mowing machine and cured like hay; after which it is carefully stacked away, in small parcels, so as to avoid much heating, and forms the very best quality of fodder.

The part of Canada here alluded to, is probably favoured with a peculiar climate, and well adapted to the growth of corn fodder. The soil also is a rich sandy or clay loam, certainly one of the best soils for the above purpose; but many localities would find it very much to their advantage to follow this course also, especially where late autumnal frosts are likely to prevent corn from maturing.

The inhabitants of Durham claim that this course of husbandry is better fitted for their country than that of growing turnips, and costs much less, especially as turnips are not generally a success with them. Many sorts of corn have been tried, from the early white Canadian flint to the tall American horse-tooth; but the latter grows too rankly and too soon attains a strong woody substance in the stalk. The medium-sized, but early, varieties are the best liked. That kind called "evergreen," or sweet late corn would, I think, answer remarkably well, as it is greatly addicted to suckering, so much so as usually to throw two or three suckers to one stalk.

The corn of this variety would not probably ripen, but the immense quantity of young green succulent sprouts would, I think, amply compensate for this want. One great advantage attending this course of husbandry is the great quantity of the richest kind of manure thus formed. Of course the yard or stables where the cattle are fed, are always well littered with straw, and the result is soon shown on the farm.

My informant states that the quantity of green corn thus grown on an acre is enormous, and the cost (except for seed) very little. Some months since I travelled on the railway with a cattle and corn farmer from the State of Maine, and he described a very similar course pursued in that State by himself and his neighbours, who depend altogether on raising cattle and making butter for the city of Boston market. He always milked fifty to seventy-five cows, bought in early spring from Canada and elsewhere, and when winter came on they were always, with few exceptions, driven off to other markets for fattening purposes. Vast herds of these cows go to New York, and are fattened on distillery slop. This food when fed hot is very stimulating, and cows that only gave in the month of November, on farm-feed, say half a gallon of milk daily, when put on distillery slop and warmly housed, at once often raise their quantity to two gallons a day, and being strippers, the milk is exceedingly rich.

Wintering over such cows does not seem profitable with the farmers in the State of Maine, who prefer buying in the spring, and selling in the fall; and I am credibly informed that the extra condition in which the animals are in the fall, on the before-mentioned food, principally formed of green corn, causes them to bring almost as much, as strippers, as they cost when fresh calved. C.

Drying Roots.

A new patented process of preparing roots for cattle feeding, by which it is claimed that they are doubled in value at a small cost, has been brought out in England The principle of the process consists mainly in drying out a portion of the water contained in the roots, and so rendering them more concentrated, while the heat used in the process (the mode of applying which makes the patent) partially cooks the roots, and so makes them more easily digestible. By thus getting rid of a portion of matter (water) of which there is an excess beyond the actual needs of digestion, the roots are rendered much more valuable to feed to fatting animals, as being less bulky in weight, while more concentrated in substance, more can be consumed by the animal in a given time, and so the process of feeding rendered shorter, without the necessity of using expensive foods, such as meal or oil cake, to quicken the process of fattening.

The thing could easily be tried here, on a small scale at first, and if found successful and profitable, those of our farmers who make the fatting of cattle or sheep during winter a part of their routine, could easily enlarge upon the primitive method we propose to give, which is nothing else than to try the baking of a few bushels at a time in one of those brick bake ovens so often found on Canadian farms.

The roots need not be subjected to great heat, but put in after the batch of bread is out, and left in till the oven cools, keeping the door shut, but allowing egress by the chimney to the vapour evolved. A slight blackening of the roots, provided they are not burnt, would not hurt them. All the valuable flesh and fat-forming elements in the roots would still remain, as does the starch and gluten in the loaf after being baked. It is said that in the experiments tried in England it was found stock would eat greedily of dried mangels and turnips, and fatten much more rapidly than on the raw roots.

Waste of Forests.

There has been, with very few exceptions, a wanton waste of the forest resources, not only of our own country, but of the entire world. Man has come to regard his early cradle, the forest, as an enemy, instead of as a benefactor. In England the prudent care of our forefathers to watch the growth of our forest trees—to secure a perennial supply of oak for our ships, as well as of yew for our bows, is altogether forgotten. The forest rights of the Crown over a district that has been wooded since the time of Julius Cæsar, the forest of Epping, have been so purposely neglected, that it has needed the very unmistakeable expression of public feeling to elicit from the Solicitor-General anything more than a joke upon wolves and bears. The 100,000 acres of forest, under the administration of the Woods and Forests, has been so admirably managed, as to arrive at the result of a rental at the rate of three shillings and six pence per acre. The wooden walls of Old England are now so much an affair of the past that it may be said that we only regard timber as necessary to ornamental landscape, or as a material for lucifer matches. It is in this country and its dependencies, and in those of our American descendants, that the laws of Nature as to the clothing of the earth with timber have been the most persistently broken. But we are far from being alone in our folly. To whatever part of the world we turn we see indications that waste and destruction bring their own vengeance in their train. Of the effects produced upon climate by the denudation of the soil there is no room for doubt. To a certain extent the influence of human labour in the thinning of forests is beneficial, but the limits between culture and destruction are rarely maintained. The increased aridity of Palestine, of Spain, and of the South of France is well known. In the former case it has been partly caused by the cutting down of the olive, a barbarous incident of warfare, merely forbidden by ancient law. In the last-named country it has been the need of fuel that has led to the denudation of so many districts, and the double evil has ensued, first, that the humidity of the climate has been reduced to a formidable extent, and secondly, that when rain does fall, in any unusual proportions, the absence of the great natural absorbing power of forest districts allows the entire product of the rainfall to be discharged at once by the natural drainage, thus causing those floods which have proved so formidable in their ravages within the last few years. The denudation of the forests of England is by no means a new grief. More than two hundred years ago Mr. Evelyn complained of the rapid extirpation, "root and branch, of all those goodly forests and woods which our more prudent ancestors left standing for the ornament and service of their country." On the confiscation of the Church lands in 1536 immense forests were cut down, and during the civil war that commenced a century later many Royal forests, as well as private woods, were entirely swept away. In France there yet exist 2,700,000 acres of State forest, earning a gross revenue of £1,740,000, and a net revenue of £1,240,000 per annum. Bavaria contains nearly 2,000,000 acres of forest; Prussia, upwards of 5,000,000; Austria no less than 13,000,000 acres, realizing an annual export value of £3,000,000 sterling. In France and Germany exist schools of forestry in connection with the service of the State, and men of a superior class of intelligence are carefully trained in these establishments for the scientific management of this important part of the national property.—*Builder.*

Gentleman Farming.

Very pleasant to talk about. Why don't one hear of gentlemen printers, gentlemen merchants, gentlemen doctors, and gentlemen everything else? The great popular mistake of those who talk of gentlemanly farming is, that they suppose the practical farmer to be a boor of necessity, and that his calling is a vulgar one, unfit for an educated mind, yet when sublimated by intelligence, education and refined associations may be made respectable! "Gentleman" farming is a rank humbug, as any other profession or trade would be, followed in the same fashion—that is, by hanging out a sign, furnishing the shop, store or office with its stock-in-trade, and then leave it to the clerks and shop boys to take care of, while the principal goes about talking politics, or spending his time in the bar-room, or fooling it away in other nonsense.—*Boston Cultivator.*

Soot.

This is an excellent manure: but, as in many other cases, one must know how to use it. It is: First—Good for all fruit trees; then, for meadows over-run with moss, and for clover. In the kitchen garden, reserve it for the onions. For other vegetables it is more hurtful than useful. Use it with moderation. In small quantities, soot produces good results; in large, it disorganizes the plants, burns and cauterizes them, eats both leaves and roots. On a rainy day, give your soil a weak dose; prudence says, mingle earth and mud with it. Above all, do not make use of it in hot and dry weather.—*La Gazette des Campagnes.*

Rank Wheat.—A correspondent wishes to know "what is considered the best treatment for fall wheat too advanced for the season." Turning on sheep to feed on the too rank growth is sometimes practised with good results.

Securing Fence Posts.—By nailing a strip of board on each side of the post at the lower end, sagging and heaving may be prevented. The edges of the boards should come even with the bottom end of the post, and project a few inches each side, being crosswise of the fence line. The projection need not be more than two or three inches on a side, and the strips not more than four inches wide, yet wider would be better.

Potatoes on the Manitou Islands.—Some of the finest potatoes that we have seen this season were grown on the Manitou Islands, in Lake Michigan, at something over 45 degrees north latitude. Parties whom we saw on the islands stated that they often let the potatoes stay in the ground all winter without digging, as the great fall of snow there in the latter part of the fall prevented them from freezing. It is also quite common there to plant potatoes in the fall that are wanted early the next season. The Colorado beetle has not yet reached this paradise of potato raisers.

When board fences become old, and the boards begin to come off, nail upright facing stripe upon them against each post, and the boards will be held to their place, and the fence will stand several years longer. Always set a post fence over a ditch, or near a good drainage, and the post will always remain dry, and will last many years longer than those standing in wet subsoil.

In the top-dressing of meadows with compost, we are adding to the soil, raising it and inviting the roots of the grass upward, thus thickening the sod. This is the most precious of manures—this thick mat of roots and compost. It will prolong the meadows, and add to the production of grain when ploughed. On a gravelly soil this compost will be improved if one of the principal ingredients is clay.

Stock Department.

Preparing Cattle for Fattening.

That loss instead of gain results in many instances, from the process of feeding cattle for the butcher, especially by small farmers and those who do not make a regular practice of fattening beasts for sale, and consequently have not acquired the practical knowledge the regular feeder finds so necessary to ensure success in the process of fattening cattle, is but too true. Much of this is due to the want of good breeding, and an adaptability to feed well, in the beasts themselves, but more of it to the want of proper preparation of the animals before they are put up to fatten.

How often do we see a miserable half-starved bovine without a particle of flesh on its bones, but what muscles will hold its frame together, and having a hard unyielding skin covered with dirt and scurf, put up to be fed for the butcher on dry hay, to which a few roots and perhaps some grain is grudgingly added. Such a beast will take months of time and a large consumption of food to bring it up to the point at which the process of laying on fat will commence; or, if highly fed on corn meal or other rich food, will put on a layer of fat just under the skin, with scarcely any flesh between that and the bones, and so be worth but little more after feeding up, than it would fetch as a store beast. Then again there are thousands of beasts put up to feed for the butcher before they have attained an age at which they can be profitably fed. Such animals, though they may be made passable enough to suit the wants of the drover or low class butcher, can only be sold at a low price and attain but small weights, while, had they been kept on till they had attained their full growth, they might be made to vie with the best and command double or treble the price.

Cattle intended to be winter-fed for the butcher should have reached maturity as regards the development of their muscular and digestive systems. With common stock this is rarely the case till they are full five years old. In thrifty, well kept, grade Shorthorns, Herefords, or Devons, the animals will be ready to fatten at three years old, and then aquire fat readily on less food than common stock at double the age. Herein lies the great advantage of an admixture of thorough-bred blood into our herds, and it should be the aim of every farmer in the land to employ thorough-bred sires as much as possible.

To get the animals in a proper condition to be fed up, they must have the run of such good pasture in the summer and fall before being put up as will bring them into the stalls full of flesh well laid on at every valuable point. This done, the process of feeding in order to lay on fat at the right point, and in the proper manner, becomes both profitable and takes but a moderate length of time, and such an animal, well managed, will bring in much more per pound live weight than one of equal size fed in the ordinary way.

Breeding Cows for the Dairy.

So great is the demand, and so insufficient the supply, of really good milch cows, that it is a wonder that more attention is not paid to the matter of breeding them exclusively. The dairymen themselves cannot well raise their own calves, as they require all the milk of their cows for the manufacture of cheese; but they can at least do something towards the improvement of this class of stock, by using only first-class bulls of pure blood, either short-horn or Ayrshire, to run with their cows during the summer. This would greatly enhance their value when they are sold off in the fall, and those who purchased in order to keep till their calves were dropped and old enough to be fed by hand, would be more likely to raise and well care for the heifer calves, from the certainty that they would prove valuable as milkers in the future. Grade cows with a strong infusion of good blood in them, always command fair prices, and usually prove better milkers and better feeders, as well as finer and larger animals, than those of purely native stock. Two crosses of short-horn blood followed by a cross of Ayrshire make the most profitable dairy stock that can be had, without at the same time going to the heavy expense of keeping a herd of thorough-breds. If some of our best farmers, in those districts that are as yet not given to cheese-making, would go into the business of breeding cows for the dairy, we think they would find it exceedingly profitable.

If good grade heifers with one or two crosses of short-horn blood of a milking strain can be had, they would form a good foundation for a herd, and by using a short-horn bull to them and afterwards an Ayrshire bull to their progeny, animals could be obtained that would combine the large size and good feeding properties of the short-horn, to which the Ayrshire cross would add the adaptability for producing milk in quantity. The short-horn blood should be stuck to, giving a cross of Ayrshire only after two or three of the short-horns have been put in.

If large well-made heifers of native stock, from good milking dams, can be had, the use of the short-horn blood will soon bring their progeny into better size or form, and then a cross of Ayrshire might be added. It is now proved that the capability of a cow to secrete milk depends greatly upon her being a large feeder and good digester, and these qualities are best obtained by using short-horn blood to cross with. Large heavy cows are the best milk producers, though they may not

give the largest proportion of butter. The diminutive Channel Island cows or the Devon are undoubtedly the best butter producers, yet they are not as profitable for general dairying as the larger short-horn or Ayrshire grades. It must not be overlooked that large heavy cows can be made most out of as beef, when their best days as milkers are passed.

By a judicious course of breeding, taking care to feed well, so as to bring the young heifers early to maturity and ready for the pail at three years old, more money can be made than one would suppose. Such animals readily command any price in reason. We have seen some sold this fall at prices ranging from $100 to $160 each. The actual cost of breeding and keeping such animals till three years old would be but little more than that of raising native stock; the principal item being the purchase and keep of a pure-bred bull, of sufficiently good pedigree to impress the high qualities of his blood upon the stock to which he is used. He must be of undoubted purity of blood, and from a milking tribe; otherwise the effort to breed a high class of cows would result in failure.

The matter of breeding stock exclusively for the dairy is one well worthy of consideration, and we are inclined to think that those who would undertake to start and establish herds with that view, would find it not only profitable, but also feel a sense of pride and satisfaction in witnessing the success of their efforts to obtain a high name that would of itself bring buyers to their doors ready to pay such prices as only really good animals can or ought to command.

Working Milk Cows.

In reference to a question on this subject to which we have already briefly replied, we may add that we have never seen milking cows worked, and doubt there being any profit in doing so, and could not recommend our correspondent to try the experiment as one having a reasonable chance of success, even when taking into account the probably increased quantity and quality of the milk which may probably arise, provided extra grain food was given in great abundance.

A gentleman from the Isle of Wight, England, says that, many years since, and before he left home, he had often seen a miserly old farmer, who occupied, as tenant, a few acres of land, doing his farm work with a cow and a donkey harnessed together; and often, when ploughing with this most novel team, he had no other driver than his daughter, who was provided with a trace whereby she assisted in difficult or hard spots. Thousands have seen this curious exhibition of combined labour, and the daughter—an old maid of about 45—did not seem to feel any decided objection to do her part.

This family lived just opposite, and within two stones' throw of the cottage of the far-famed Dairyman's Daughter, whose life has so conspicuously figured in numberless tracts.

Almost all the members of this woman's family worked at intervals for our informant, and consequently he had many opportunities of seeing the above extraordinary team at work, but no good ever appeared to have resulted therefrom.

Stock Need the Best of Care Now.

We believe that, as a rule, stock receive the shabbiest treatment of the year during the late fall and early winter. And this is the very period when they should have the best care. Every farmer knows that it is "half the battle" to bring his stock through to steady foddering in good condition. If a flock of sheep comes to the barn in December, pinched and scrawny, it will leave the barn in the spring thinned in numbers, with wool loose and ready to be pulled off by the first bramble it touches, and thus depreciated more than the cost of its wintering. If the cows come to the stable and foddering, pinched and thin, by reason of frost-bitten pastures and heavy milking, the owner need not be surprised if half of them loose their calves or their lives during the winter. In fact, may not the treatment of the cows during the late fall and early winter, be one of the chief causes of the growing frequency of abortions in dairy districts? The dairyman is anxious to make his cows pay him all they will. He has good excuse for being greedy, we admit. Even the consumers of butter and cheese, who are accustomed to complain so loudly of the high prices of those articles, must acknowledge it, too, after reading the exhibit of their cost, made at the last meeting of the Central New York Farmers' Club. Yes, the dairyman is in no danger of getting suddenly rich, even if successful in getting the largest possible yield from his cows. But many of the devices that he resorts to, for compassing that end, are crying examples of mistaken economy. They are suggested by his greed rather than his good sense, and result too frequently, as measures adopted by greed generally do, in killing the hen that lays the golden egg. He thinks there is no need of foddering his cows until the pastures are covered with snow, and the shivering animals stand lowing about the barn. As long as they will roam over the pastures, picking at the frozen and innutritious tufts of grass, he thinks they are doing well enough. They shrink in their mess badly, but he feeds them with apples, or pumpkins, or leaves from his root crops, and they regain their usual flow of milk. Now they are certainly well enough. But he forgets that he is burning the candle at both ends; that he is trying to "eat his cake and keep it, too," though he is temporarily succeeding. When he comes to stable his cows for the winter they are lean and weak. Pretty soon, some of them begin to abort. He thinks they need heartier food. He gives them a little meal, in addition to his best hay; for he has now fed out all the "odds and ends"—the poor corn-fodder and the worst straw. But this sudden change in the diet only aggravates the difficulty. It makes his cows feverish, but not healthy and strong. Still more abort; or, if they escape this, and drop their calves alive, they fall victims to milk-fever, black-leg, pleuro-pneumonia, or some other of the many ills that badly treated cows become heirs to. He is perplexed. He can see no reason why his herd should be so afflicted; and he very philosophically concludes it is his "luck," when there is no "luck" about it; only carelessness and "mistaken economy."

Of course, we do not mean to assert that cows, with the best of care, will escape all diseases and mishaps; nor do we wish to put forth the theory that abortion is attributable only to improper feeding in the fall, or at any other time. But we do believe and assert that every farmer loses ten times as much as he gains by scrimping his cows during the last of the fall and the first of the winter, or by leaving them to shift for themselves. As soon as the cold rains of November come on, they should be stabled every night and given a light foddering of good hay or cornstalks every morning. Never should they be allowed to sleep out after snow begins falling, or left to the pickings of frozen pastures. Cabbage leaves, leaves of root crops, apples and pumpkins may be profitably fed, if other food is also given to sustain and build up the muscular system. But milk-secreting food, when given in excess, weakens the animal and often causes her serious injury.—*Utica Herald.*

On Pig Breeding and Feeding.

Some of the most prominent breeders of swine at the south-west had a discussion recently, at the meeting of the St. Louis Farmers' Club, on the subject of breeding and feeding swine. The qualities and adaptability of several different breeds were thoroughly discussed, and the general conclusion seemed to be that the Berkshire was in every way the most profitable breed, and the most to be depended on. Medium-sized animals seemed to obtain the preference. The Poland and Magie found many friends, but it was admitted that they were not yet sufficiently established to rank as a pure breed, and that a cross of the Berkshire, the Chester White, or any other kind of pig common to that section, upon them, produced a better and more profitable animal to feed than anything else that had yet been tried.

In answer to the question as to how the Berkshire itself in its purity had proved successful as a feeder, it was said that the breed had as yet been too valuable to use for crossing on other stock to be made into pork, but that some would be fed this fall to test the matter. Those that were now being fed were estimated by their owner to go seven hundred pounds each dressed. They give a larger weight for their size than any other breed. The crosses obtained by using Berkshire boars to sows of other breeds were remarkably thrifty, and easily kept. The Berkshires were admitted to be good breeders and excellent nurses, seldom if ever destroying their offspring, while the Essex were said to be very uncertain as breeders and nurses, and the other large breeds of the south-west were much given to destroying their young.

It was stated that corn should not be fed to young pigs, and that even fatting hogs did better upon a mixture of oats and corn, or several kinds of grain together, than on corn alone.

Scalding the feed seemed to be considered preferable to grinding it, and feeding often, not less than five times a day, better than giving the animal large quantities at a time.

One fact strongly in favour of the Berkshires came out, namely, that they were exempt from that scourge of pig-breeders of the West, hog cholera, as also were the Essex. These fixed breeds were said to have a higher vitality and better constitutions to resist unfavourable climatic influences than those of a less fixed type. Added to this, they were eminently a grazing breed, and will grow fat on clover alone, where a common pig would starve for want of grain or animal food. As one speaker said, "they did not know what grain was," to which an advocate of the Chester Whites replied, "Starve them to it."

The Selection of Breeding Stock.

is somewhat singular that, while the country abounds with well bred animals of every kind, horses, cattle, sheep and pigs, there is yet such a superabundance of wretched breeds to be met with in every direction. To a certain extent bad land accounts for a portion of this, inducing weediness even in animals of good blood, and whose form under more favourable conditions would be all that could be desired; the proof being that, when removed to kindlier pastures, if done before they become stunted, they rapidly fill up and become useful stock, healthier and hardier probably than others reared under more favourable conditions. Those who farm poor land are also more or less indifferent as to the necessity of procuring good blood, believing that the common breeds are hardier, and as in the case of milch cows give a greater return on poor pastures than better bred animals could possibly do. Bad land, however, does not account for all the poor stock to be met with; on the contrary, a considerable proportion of it comes from land of average quality, and which is quite capable of carrying animals of much greater weight and value than many of those that are found upon it. The great natural law that "like begets like" seems in such cases to be entirely overlooked, animals of both sexes continuing to be bred from that are totally unfit to be used for reproductive purposes. A farmer doing this betrays a want of attention and indifference to the furtherance of his own interests highly reprehensible, and if his stock is extensive he must in the long run suffer severely. Using male animals of mixed blood is a most prolific source of injury, and of course actual pecuniary loss, whether in the herd or flock. Deterioration may not be immediately noticeable, but when a certain point has been reached, improvement must stop; and in the progeny of cross-bred animals there must, and always will be, found a number of weaklings not worth the trouble of rearing.

Whatever the class or character of the dams, the continued use of sires of a distinct breed, capable of transmitting a family likeness, should constantly be persisted in; the man who does so finding his stock of various breeds of animals yearly increasing in value, the receipts correspondingly raised, and the occupants of his pastures, stables or stalls, wonderfully improved in appearance.

Whether they attend to it or not, we find most men admitting the influence of a well-bred sire on the character and quality of the future offspring; but, strange to say, comparatively little stress is laid upon the influence for good which is exerted by the dam on her young, when she herself is of good quality and well descended. When both parents are good, progress is rapid; and by holding over for breeders only the young of the best animals much time is saved, and the required amount of perfection is reached in a very limited number of years. Once looked to, this point will ever after be considered one of the most vital importance, and will on no account whatever be neglected or overlooked. To any one conversant with stock in large numbers, the influence of the mother is strikingly apparent in certain members of each class, their produce year after year exceeding in value that of every other animal of the same kind, and when sold brings proportionately more money. Thus, for instance, a cow will sometimes breed calves for a succession of years exactly the same colour, form and general character, no matter if the sire is changed each year; and her progeny again will transmit to their own offspring the same characteristics, but in an improved degree, if the necessary measures have been attended to with this view. Families are thus founded, and men intelligent enough to profit by improving a good strain which have come in their way—it may be quite accidentally in the first instance—have gained for themselves a name and acquired fortunes. To breed from females which have proved themselves indifferent nurses, and whose progeny, however handsome they themselves may be, are always amongst the culls of the flock or herd, is very short-sighted policy, and detracts very materially from the prosperity of those who will not take the trouble of marking all such animals, and getting rid of them on the first favourable opportunity. Hardiness, by which general term a great deal of meaning is expressed, should never be lost sight of by the breeder, but on the contrary carefully attended to, as it is a quality of the utmost consequence, enabling them to withstand the vicissitudes of the weather, to keep up condition at periods when the greatest foresight cannot prevent a scarcity of food, to be always in good health, and to be able to breed animals of sound, healthy and hardy constitutions.—*Mark Lane Express.*

Weaning Pigs

Some farmers wean the pigs a few hours after birth, and turn the sow at once to the boar. The best mode, however, is to turn the boar into the hog-yard about a week after parturition, at which time the sow should be removed a few hours daily from her young. It does not injure either the sow or her pigs, if she takes the boar while suckling; but some sows will not do so until the drying of their milk.

The age at which pigs may be weaned to the greatest advantage, is when they are about eight or ten weeks old; many, however, wean them as early as six weeks, but they seldom turn out as well. They should not be taken from the sow at once, but gradually weaned. At first they should be removed from her a certain number of hours each day, and accustomed to be impelled by hunger to eat from the trough; then they may be turned out for an hour without her, and afterwards shut up, while she also is turned out by herself. Subsequently, they must only be allowed to suck a certain number of times in the twenty-four hours; perhaps six times at first, then four, three, and at last only once; and meanwhile they must be proportionately better and more plentifully fed, and the mother's diet in a like manner diminished. Some advise that the whole litter should be weaned at once; this is best, unless one or two of the pigs are much weaker and smaller than the others; in such case, if the sow remains in tolerable condition, the feeble ones might be suffered to suck for a week longer; but this should be the exception, and not the general rule.

Pigs are more easily weaned than almost any other animal, because they learn to feed sooner; but attention must, nevertheless, be paid to them, if they are to grow up strong healthy animals. Their styes must be warm, dry, clean, well-ventilated, and weather-tight. They should have the run of a grass meadow or enclosure for an hour or two every fine day in spring and summer, or be turned into the farm-yard among the cattle in the winter, as fresh air and exercise tend to prevent them from becoming rickety and crooked in the legs.

The most nutritious and succulent food that circumstances will permit should be furnished them. Newly-weaned pigs require five or six meals in the twenty-four hours.—In about ten days one may be omitted; in another week, a second; and then they should do with three regular meals each day A little sulphur mingled with the food, or a small quantity of Epsom or Glauber saults dissolved in the water, will frequently prove beneficial. A plentiful supply of clear, cold water should always be within their reach; the food left in the trough after the animals have finished eating, should be removed, and the trough thoroughly rinsed out before any more is put into it. Strict attention should also be paid to cleanliness. The boars and sows should be kept apart from the period of weaning.—*National Live Stock Journal.*

Canadian Horses for the Cavalry.

To those who are fond of sneering at our Canadian breed of horses (and of whom there are not a few in Canada), the following public testimony, borne by a man whom the *Mark Lane Express* styles "one who has evidently much experience of the countries of which he speaks" may be some answer:—"As regards the merits of the horses as troopers, in the year 1842 I saw a considerable number of these animals that came home in the 1st Dragoon Guards and the 7th Hussars from Canada. I rode a great many of them, and I say unhesitatingly that they were the best troop horses I ever rode in England—up to great weight, very shapely, and fine free goers, with splendid action. They were bought for about £25 each."

The Value of Straw as Fodder.

In the remarks we have made regarding the value of dry corn fodder, it was stated that it has been put in mows with wheat straw in our barns, and that the straw and corn "butts" have been consumed together by our herd of cows, causing a copious and well-sustained flow of milk during the winter months. These remarks have led to many inquiries from our farmer readers with regard to the nutritive value of wheat and other kinds of straw. It is certain that straw has been under-estimated in this country by grain-raisers, and that a source of profit has been to a considerable extent lost from this circumstance. One hundred parts of wheat straw, as produced under ordinary conditions in this country, contain:—

Water	13.33
Oil, etc	1.74
Albumen, etc	1.28
Sugar, mucilage, extractive matters, etc	4.26
	19.40
Digestible fibre	1.13
Soluble inorganic matter	1.65
Insoluble proteine compounds	54.13
Woody fibre	3.08
Insoluble inorganic matter	
	100.00

It will be seen that wheat straw contains about 30 per cent. of assimilable food, or food capable of nourishing animals. It contains as much albumen and proteine compounds as the ordinary run of hay. Woody fibre is, however, largely in excess, and there is a far less quantity of sugar, mucilage, etc., than in the hay of our meadows. The kind of straw which approaches nearest to good upland hay is oat straw cut before it is ripe. The order in which the different kinds of straw stand relatively, as regards nutritive value, may be presented thus:—

Oat straw,
Barley straw,
Wheat straw,
Rye straw.

Unquestionably it will be for the interest of farmers in most sections to diminish the amount of straw used for litter and increase its use for fodder. In many of the Northern States rye straw is of equal value with the best quality of timothy, as it is used largely for bedding horses in towns and cities. Of course, where straw commands such high prices, and is of such ready sale, it would be absued to feed it to animals.

We must not be understood in these remarks as holding to the view that any kind of straw can supersede the use of good hay and grain, but rather that it contains a sufficient amount of the elements of nutrition to make it a valuable substitute for these usually more costly products.—*Boston Journal of Chemistry.*

Captain Gunter, says *Bell's Weekly Messenger*, has suffered a great loss in the death of a young bull, Fourth Duke of Wetherby, by Third Duke of Wharfdale, from Duchess 92, the beautiful cow which Mr. M. H. Cochrane vainly tried to buy for 2000 guineas.

Mr. Brucre has sold to Mr. Cochrane, for 500 guineas, the Shorthorn cow Star Queen. She was at the time of sale in calf to Sir Windsor Broughton (27507), the son of Prince of the Realm (22627) and Windsor's Queen by Windsor (14013).

Several thorough-bred cattle of the Durham, Devon, and Ayrshire breeds, as well as other live stock, were purchased at the late Provincial Exhibition for Nova Scotia, under authority of the Agricultural Bureau of that Province.

Musty Oats.—A South Carolina correspondent of the *Farmer and Artizan*, after reporting the loss of a horse, supposed to result from eating musty oats, says: "I am certain more horses die in the South from eating damaged oats than from all other causes. As the oats are cut rather green, and often with many green weeds among them, it is very difficult to keep them from moulding, more or less in the centre. Many animals die from this cause, which are supposed to have had blind staggers, as in the case of mine. Another horse recently died near me in the same way, after being fed on oats mostly sound, but some of the bundles musty in the middle."

The raising of Cashmere goats for their wool has become an established pursuit in Nebraska. One gentleman has a flock of 200, and his success in raising them has induced many others to adopt the breeding of that valuable stock as a regular pursuit.

Death of Cattle by Smut.—A correspondent of the Black Earth (Wis.) *Advertiser* says:—"For the benefit of those who avail themselves of the usual benefits of corn fodder as feed for stock, I wish to state through your paper, that Mr. Timothy Lee, of Dazomanie, lost by death, on the 12th instant, one cow and two heifers from a cause that at first appeared quite mysterious, but on examination of the stomach, smut and corn were found in such an abundance that it was no longer a mystery, and the conclusion was that they died from the effects of a poison generally known as corn smut. The smut was eaten on the hill where the corn had been husked, except such ears as contained that excrescence which Mr. Lee considered worthless and harmless."

Variety of Food for Hogs.—In an experiment detailed in *Deitz's Farm Journal*, where hogs were fed on cooked potatoes and oats, by the iodine test, the excrement showed that a large portion of starch was passing off undigested. By the addition of a small amount of peas to the feed, the iodine test showed that all the starch was appropriated to the animal economy. Experience has demonstrated that a variety of food is essential to the perfect development of animals. When hogs are fed for any length of time on the same food they become "glutted," and the addition of even a single article of food to what they have been accustomed to, shows a marked improvement. If they are fed on corn they should have pumpkins or potatoes; access to grass should be allowed them when they do not have a variety of food.

Cut Feed for Horses.—An accurate farmer has furnished the *Country Gentleman* a statement of his experiments with feeding cut feed and meal to his horses, accompanied with weighing and measuring. He cuts oat straw about an inch long with a raw-hide cylinder machine, and this chopped straw is then treated with corn meal bran, and mixed in about equal quantities as to weight, so that each horse has about a bushel of cut feed, and three quarts of the meal and bran, twice in each day. Sometimes hay is cut instead of oat straw, or both are mixed. It is found that 200 lbs. per week of this mixture of corn meal and bran, added to the cut feed, will keep a pair of working horses in the best condition. This, he is satisfied from experiment, *is less than two-thirds the cost of keeping them on uncut dry hay and whole grain.* The corn meal alone is not so good for horses as when diluted with bran. An excellent meal is made of ground oats. The fodder is cut by horse power on stormy or spare days, and stored in large bins, so as to furnish always a surplus on hand.

Veterinary Department.

Castration in Horses.

We are frequently asked the question what is the safest time to perform the operation of castration. As to the season, there is a considerable difference of opinion, but from our own experience we prefer the months of May or June, and consider that the operation is most successful in yearlings. There are various methods of performing the operation. In olden times the function of the testicle was destroyed by pressure, or by removing part of the seminal duct (*vas deferens*), and also by the barbarous practice of tearing out the glands. These methods, however, have been long abandoned, and the operation is now usually performed in a more surgical and scientific manner.

The common methods of performing castration on this continent are by compression either with or without caustic; by cauterization or the firing iron; by ligature; and by torsion. In aged horses, before operating, it is advisable to prepare the subject by feeding for a day or two on bran mashes, and giving very little bulky food. By having the bowels comparatively empty there is less danger in throwing the horse and securing him, and in all cases, immediately before operating, the scrotum should be carefully examined with the view of detecting hernia or rupture, because, if hernia existed, and an incision were made through the serous coat of the testicle (*tunica vaginalis*), the imprisoned bowel would at once protrude, and might defy all efforts to return it.

After examination for hernia, the horse should be thrown and secured upon his back, with the hind legs pulled forward, and firmly attached. It is advisable to secure him firmly, as by doing so it will prevent struggling, and at the same time the operation can be more easily performed. The testicle should then be taken hold of with the left hand, and an incision made through the scrotum parallel with its division or *raphe*, exposing the testicle, which must be drawn carefully out for a little distance; but on no account use any violence. If the caustic clams are to be used, the *cremaster* muscle should be detached, and the clam placed upon the cord and firmly secured. The testicle may then be removed, and in the course of thirty-six hours thereafter the clams may also be taken off. The grooves in the clams are usually filled with a caustic paste formed of corrosive sublimate, fleur and water. Compression alone will have the desired effect, but the vascular communication is destroyed more rapidly with the aid of the caustic.

In Britain the operation is usually performed with the aid of the firing iron. An incision is made through the scrotum, and the testicle pulled out, and a large temporary clam applied around the cord; the testicle is removed, either with the knife or iron. We prefer the former. The end of the spermatic artery is seared by the cautery, the clams are removed, and the operation is over.

When the ligature is used, the operation is performed in the same manner as by the iron, with the exception that the end of the spermatic artery is taken hold of with a pair of forceps, and a ligature is applied and then the clams removed. Of these three methods of operating we prefer the cautery or firing iron.

Obscure Lameness in Horses.

Most horsemen have at some time or other experienced the annoyance of having a journey interrupted by the sudden occurrence of lameness in an animal which, up to the time, had done good service without showing any signs of unsoundness. Not less annoying than the accident itself is the mystery which attends the cause of defective action. The horse may be as lame as if he had broken his leg, but no signs of injury are apparent; and under the circumstances all sorts of gloomy speculations are indulged in by the owner. The animal must have been unsound before, and the disease is now becoming manifest. This idea naturally occurs to the mind if the horse has not been long in the owner's possession, and the one solitary gleam of comfort which he feels under the disagreeable circumstances of his position is associated with his determination to return the brute at the earliest opportunity. If the horse is an old servant, and there is no chance of falling back upon an unsoundness of long standing, the rider concludes that something has given way, perhaps in the foot or the shoulder, or, if the hind leg is affected, that a joint has slipped. It is consoling to reflect that none of these serious evils is usually present in the instances of sudden attacks of severe lameness to which we have alluded.

Extensive injury to important structures does sometimes occur without an apparently adequate cause, and we have several times referred to such injuries as compound fractures of bones of the extremities from the concussion resulting from unconscious movements, fractures of the bones of the back and ruptures of muscles during violent efforts to rise from the ground, sprain and even rupture of tendon and ligament during rapid movements; but in all these cases the nature of the mischief is in some degree apparent. The injured part is tender to the touch, heat and swelling soon appear, and there is seldom much difficulty in deciding at once as to the seat of the disease. Lameness, equally as severe as that which arises from sprain of tendon or muscle, often happens independently of these injuries; and to such cases the term "obscure lameness" is fairly applicable. Now and then the recovery from the lameness is as sudden as the attack. This fact was particularly well exemplified some time ago in the case of a gray pony, which, while being quietly ridden along a level road at a foot pace, became all at once so lame that the rider dismounted and examined the limb—the near fore one—in expectation of finding some severe injury in the shape of fracture or dislocation. Nothing, however, could be discovered at the time to explain the lameness. The pony was, with much difficulty, taken to a forge about a quarter of a mile distant, and the shoe was removed. No injury, however, was detected in the foot, and a second careful examination of the limb did not lead to the detection of the slightest sign of tenderness, heat, or swelling in any part. Treatment was of course out of the question, as no disease was apparent; and the animal was therefore left to his fate till the next day, when, if we remember correctly, he was found to be sound, or nearly so; at any rate, he was at work again in a day or two after the occurrence which has just been narrated.

Sudden and severe lameness often arises without the action even of those common causes which are in operation while an animal is at work, such as concussion, sprain, treading on stones or other projecting bodies. A horse may be left in the stable at night in good health, and in the morning may be found incapable of moving over in the box or stall. In such cases the hind extremities are most commonly affected, a circumstance which is suggestive of the nature of the accident that caused the lameness. When a horse is made to rise suddenly from the recumbent position, it is very common for one hind leg to slip backward for some distance, in consequence of the foot missing its hold upon the floor of the stable. Perhaps in ninety-nine cases out of every hundred no harm results, the animal gets up and moves with his usual freedom; but in the hundredth instance sprain of muscle or ligament is caused, and the horse is suddenly reduced to an almost helpless state from an injury which, unless the accident was observed, can only be surmised to have occurred.

From the position of the structures which are affected, the immense mass of muscle which exists in the hindquarters, and the depth at which the joints are placed, it is nearly impossible to effectively manipulate the parts, and it is only by careful observation of the animal's action, and his behaviour while the parts are being examined, that any opinion of the situation of the injury can be formed.

In reasoning upon the probable causes of those obscure cases of lameness which are unaccompanied by distinctive symptoms, we constantly ignore the very valuable teachings of our own experience in reference to accidents which happen to ourselves or to our

neighbours. A man steps freely off his own doorstep in the morning, and, without any warning, finds his ankle suddenly twisted on one side. For a few minutes he suffers intense pain, and, if he moves at all, his action is of a character which in a horse would be called "dead lame." After a time the intense pain subsides, but for some hours, perhaps for some days, the individual limps a little even in the accustomed walk; a run he dares not dream of attempting. In comparing defective action in horses with the same or similar condition in men, it must be remembered that the lameness which is shown in the walk must be very severe indeed in a horse; and lame men never as a rule try a trot, not being impelled thereto by the sound of a whip in the rear. In these accidents occurring to men, there is often considerable difficulty in detecting symptoms of injury; the painful ankle is perhaps not very susceptible to the influence of pressure; the most careful inspection fails to discover the slightest signs of inflammation, and the surgeon, if left to his own resources, would often be as much puzzled as the veterinarian; but, as it is, the human patient settles the whole difficulty at once by the use of his tongue, doing with a word more than the horse can do by his action at various paces performed under compulsion, and at the cost of considerable suffering to himself.

A vivid recollection of the numerous trifling accidents which cause temporary lameness in ourselves would often assist our conclusions when we are seeking to detect the cause of sudden and obscure lameness in horses; and there is no doubt that in many cases we should hit upon a solution of the mystery, notwithstanding the absence of definite evidence. Horses are in the habit—some of them regularly—of striking one leg with the opposite hoof, and many sudden attacks of temporary lameness are due to this cause; an accidental change in the position of the legs during progression may expose a sensitive part of a limb to a blow from the hoof or shoe of the opposite leg. Over the most prominent part of the fetlock-joint a large sentient nerve passes, and a slight bruise on this part would cause intense pain without leaving any marks of the accident.

Sudden slips may occur while the horse is going, and considerable pain may be thus inflicted, although nothing of an unusual kind may have been noticed in the horse's movements.

Violent concussion may affect the structures of the foot, or some of the joints, fetlocks or hocks, for example, without producing any external derangement at the time, and probably not at any subsequent period of the duration of lameness. Cases have recently occurred of horses becoming suddenly lame, and remaining lame for weeks, without at any time showing symptoms of active disease.

Treatment of obscure lameness, in the first instance, should be merely expectant in its character, the object being to wait for development of symptoms: with this view, the common practice is to give a dose of physic, lessen the quantity of food, and put the animal in a loose box for a day or two. By the time the purgative has ceased to act the animal may be sound again, or so far improved as to justify a continuance of the rest for a few days longer. If the lameness continues, or becomes more severe than it was at first, it is obvious that something more than a slight injury or temporary derangement exists, and the nature of the mischief must be ascertained before any further treatment is attempted; and it is far better to take advantage of the highest professional skill and experience that can be obtained than to grope in the dark, and perhaps lose a valuable animal that might have been saved by timely care.

Carrots for Horses

To the Editor.

Sir,—I grew a large quantity of carrots the present season for the purpose of feeding my horses with them. A day or two ago, however, I was told that they were unwholesome for horses if fed to them regularly as a substitute for grain, and that they should only be given occasionally. I have also been feeding them turnips. I have long believed both carrots and turnips good for horses when moderately, though regularly, fed to them with hay. Will you please enlighten me on the subject?

HORSEMAN.

Reply—Carrots, when given in moderate quantities, once or twice a day, along with an allowance of grain, are found beneficial, principally by assisting the proper digestion of more nutritious food. We have known horses, not doing heavy work, kept in good condition on carrots and hay; but if the roots are given in large quantities to horses that are working hard, they would be deficient in nutriment and might have an injurious effect.

Rheumatism in Sheep

This disease consists in a peculiar inflammation of the muscles of the body, very frequently causing considerable pain when they are called into action. It is usually caused by exposure to cold, and sometimes shifts from one foot to another, occasionally degenerating into a slow or chronic form, and attacking the sinews, ligaments and joints, as well as the muscles. The neck and loins are the parts most frequently attacked, either separately or combined. The former affection causes the head to be crossed in a bent position, and the latter produces considerable stiffness and weakness of the loins.

The treatment should consist in removing the animal to a comfortable place, giving an active purgative, such as two ounces of epsom salts dissolved in warm water, with a drachm of ginger and half an ounce of spirits of nitrous ether. A stimulant, such as hartshorn and oil, or opodeldoc, should be well rubbed over the affected part; and if the disease assumes a chronic form, a seton should be inserted near the part.

The Dairy.

Winter Treatment of Milch Cows.

The great increase in the manufacture and consumption of cheese within the past few years renders dairy farming a more certain and profitable branch of husbandry than grain-growing, especially in those sections where grass and water are sufficiently abundant, and the soil adapted to carry pasturage of a high quality. But the man who keeps a number of cows through the summer for the sake of the profit to be made out of their milk rarely raises enough of hay and roots to enable him to keep them over the winter, and as a consequence sells off the larger portion as soon as the cheesemaking season ends, replacing them by others when grass again comes in. Most of these cows sold off in this manner, in autumn, are bought up at low prices by farmers who have a surplus stock of hay and roots to feed out, and who expect to make a profit in three ways out of their investment; namely, first, by making manure for their farms; second, by the sale of the calves obtained from the cows; and lastly, by the increased value of the cows themselves, when ready in spring to be again resold to the dairymen.

Now, if the cows are well fed and taken care of, their increased value in spring would alone amply repay the cost of keep, added to which they would produce more and richer manure, and their calves, being strong, healthy, and full of flesh, would command a high price from the butcher, and if heifers got by a thoroughbred bull, would be of much greater value to raise and afterwards sell to the dairymen.

We are not advocates of the practice of keeping cows that are to calve in spring at the milk-pail during the previous winter. Our own experience has taught us that the small amount of butter to be obtained at great trouble and cost from such cows during the winter season, even though it bring a high price, is the most unprofitable production of the farm.

What is gained by making butter in winter for sale is more than lost by the increased cost of keep and loss of strength and condition of the cow. Her food ought rather to go towards developing the calf, and if she is not made to bear the additional strain upon her of giving milk at the same time, a moderate amount of food will keep her in thrifty and healthy condition. The aim should be to keep all the milch cows through the winter well housed, and so fed that they come out in spring at calving time fleshy but not fat, and with clean smooth hides, free from lice or scurf.

The brush and comb should be freely used, and the animals kept warm and clean, with plenty of straw to lie on.

The wintering of cows in the straw yard, as too often practised in Canada, is a most barbarous custom, and a mistaken economy, generally resulting not only in suffering to the animals, but also in direct loss to the farmer, as his profits, if any, are not to be compared with what he can obtain by liberal feeding and treatment.

No good farmer will keep more stock than he can find abundance of food, shelter and care for, and he who does will usually suffer loss. Generous keep and care are always well repaid, both in the increased value of the animals and the manure obtained from them, as well as a feeling of pride and satisfaction to the farmer at seeing his animals always thrifty and healthy.

Good hay, with a large admixture of clover in it, and the addition of half a bushel of roots per day, is the best feed for cows in winter. If roots are not to be had they should get a mess of cut straw and chopped rye or peas, mixed together and steamed or boiled. This may be allowed to stand till slightly fermented before using. The cows should have a feed of them at least every other day. We do not think exclusive feeding on soft or cooked feed is advisable, as it has a tendency to soften their gums and cause them to suffer a loss of teeth, especially in those that are past their prime as regards age.

Winter Dairying.

When a farmer resides near enough to a city or town to make it profitable to keep cows in milk through the winter season, and has the proper facilities for doing so, he should endeavour to make it a point to have only good cows and feed them well.

The mode of feeding to be adopted will in a great measure depend on whether it is designed to sell the milk, or to sell the butter produced from it only. In the former case the main object is to obtain a large flow of milk without regard to its richness. To do this, the cows need to be fed to a large extent upon food containing a considerable proportion of liquid elements, to which bran must form the chief addition. The hay or straw used should be cut and pulped with turnips or beets or mangels. The usual proportion of bran in this case is four pounds per cow each day, given at night.

If the pulped mixture can be fermented before feeding to the cows, they will give a larger yield of milk, with no taste of the turnip, than if fed unfermented. If the roots can be cleaned or boiled they will be still better and go further.

Where butter making is an object, roots are to be avoided, and good sweet hay given, with the addition of three pounds per day of pea, oat, or barley meal to each cow, given raw, or if the hay is cut, which is better, the cut hay should be moistened with water, and the meal mixed into it. Unless some food rich in nitrogen is given to milch cows, it is but a troublesome and unprofitable undertaking to attempt to make good butter from their milk during the winter season.

Cheese Factories in Europe.

The factory system of cheese-making is steadily progressing abroad, not only in Great Britain, but also in other European countries. A recent article in the London *Field* states that up to the date of October 10th one hundred tons of cheese had been made at the two factories established in Derbyshire, and twenty-two tons had been sold at an average of over 80 shillings per cwt. The article says, in continuation:—

"From what we can gather, only a very few of the prime farm dairies have touched that figure. One point worthy of being recorded is the fact that in the whole make of the two factories there has not been one cracked or unsaleable cheese. A day or two after the Derby factory was opened, an experienced farmer and cheesemaker, on looking at the first day's make, remarked that he would like to bring his glass and pipe, and sit quietly and see that cheese tumble to pieces, pointing to one rather larger than the rest. That same cheese was sent to London on the 9th of September, and our friend might have been still enjoying his pipe and glass, without seeing any outward change in its appearance. The factory system may be slow in taking root on English soil, but that it will eventually do so, to the exclusion of all others, is highly probable. Once fairly established, the farmer will as soon think of returning to the flail and the reaping hook, or the pillion and panniers, as of returning to make cheese in the farm kitchen."

The writer proceeds to state that a Russian gentleman has lately visited these factories, and spent six weeks in familiarizing himself with their operation. He has taken back with him to Russia all the necessary plans, and will commence operations there on the American system next spring. Another, from Denmark, is now investigating the subject, with the prospect of doing the same thing in that country.

Right and Wrong Way to Milk.

The *Irish Farmers' Gazette* publishes the following from Prof. Dick, of the Edinburgh Veterinary College, on the manner of milking:—

"The operation of milking is performed differently in various parts of the country. In some the dairy-maid dips her hand into a little milk, and by successively stripping the teat between her fingers and thumb unloads the udder. This plan, however, is attended with the disadvantage of irritating more or less the teat, and rendering it liable to cracks and chops, which are followed by inflammation extending to the rest of the quarter. This accounts for the disease occurring more frequently among the cows under the charge of one milker than it does in those under the charge of another; and as this practice is more common in some parts of the country than in others, it also accounts for the disease being more common in these parts. This plan of milking, where the irritation is not sufficient to excite the extent of inflammation to which I have allnded, frequently produces a horny thickening of the teat, a consequence of the cracks and chops which renders it more difficult to milk than when in its natural state, and, at the same time, predisposes to inflammation when any cause occurs to set it up.

These effects may be, and are, almost entirely avoided, by the most scientific plan of milking adopted in other parts of the country, where, instead of drawing down or stripping the teat between the thumb and fingers, as I have stated, the dairy-maid follows more closely the principles which instinct has taught the calf. She first takes a slight hold of the teats with her hand, by which she merely encircles it, then lifts her hand up so as to press the body of the udder upwards, by which the milk escapes into the teat; or if, as is generally the case when some hours have elapsed between milking-times, the teat is full, she grasps the teat close to its origin with her thumb and forefinger, so as to prevent the milk which is in the teat from escaping upwards; then, making the rest of the fingers to close from above downwards in succession, forces out what milk may be contained in the teat through the opening of it. The hand is again pressed up and closed as before, and the milk drawn easily and freely, without the tugging and wrenching inflicted by clumsy milkers."

Blankets on Milk Cans.

Mr. Gardner B. Weeks, of New York, has addressed a communication to the Massachusetts *Ploughman*, condemning the practice, which has been advocated by some, of covering milk cans that are to be taken to the factory with thick woollen blankets or buffalo robes, with a view of keeping out the heat of the sun. In his article he says:—

"That the cans should be protected from the sun's rays, I admit; but it should be done in the way of a raised awning, or other appliance lifted above the cans. If a thick blanket or robe be laid directly over a can of milk from which the animal or natural heat has never been removed, and the milk then drawn any considerable distance to the factory, it will ordinarily so far injure the milk that it will sour in a few hours.

"I have had just this experience the present season at my creamery. Milk brought from a farm three miles distant from the factory caused trouble to the cheesemaker day after day by souring prematurely. On in-

quiry I found that the driver of the milk team had lately adopted the habit of throwing a buffalo robe over his cans as a protection from the sunshine. As a consequence, this milk soured before morning, and soured all the milk in the vat into which it was put; this, too, notwithstanding a large stream of cold water—52 degrees—was passing around the vat all night. On directing the removal of the robe as a covering, the trouble ceased at once, and has not recurred. This quite accords with similar experience which I have had in years before.

"In the cold part of the season, even in frosty weather, when milk is drawn but once daily, I have had the night's milk very much injured, sometimes quite soured, because the dairyman had placed the can cover closely upon the warm milk, and then set the can in a closed room or shed where the cool night air could not strike it. The can should have been placed under cover to keep out rain, etc., but in an airy place, and the cover should not have been put on at all.

"Whether there is, or is not, as much importance attaching to the "odour" question respecting freshly drawn milk as some contend, it is clear to my mind that milk must have access to pure air in order that it may be kept in good condition, even for a few hours.

"Frequent stirring of the milk in the can with the dipper, while the milking is being done, and up to the time the cans start for the factory, will do much towards reducing the temperature by aerifying the mass of milk.

"If milk is in any way thoroughly cooled —say to 60 or 65 degrees—then by all means let the advice of your correspondent be followed and the milk covered. In default of this cooling, let the can be protected by a raised awning which will allow free play to the wind. If neither can nor will be done, let the can go without any protection other than the usual tin cover."

The Largest Dairy in the World.

In his notes on the Pacific coast, Mr. X. A. Willard, of the *Rural New Yorker*, gives an account of what he calls "the largest butter dairy in the world." It is situated at Point Reyes, in Marion county, California. The ranch has a coast range of fifty miles, and contains seventy-five thousand acres. He states that about 3,000 cows are in milk on the estate, and they are divided up into twenty-one dairies, averaging about one hundred and fifty cows to each. The proprietors commenced improving their stock about the year 1858, by crossing common Eastern cows with two thorough-bred Shorthorn bulls of good milking family, brought from Vermont at a cost of $10,000. One of the Vermont bulls was an exceedingly fine one, and his stock proved to be excellent milkers. A year or two after, twenty-two head of Devon cattle were purchased and introduced among the herds. This breed did not prove satisfactory, and it was discarded, and in 1865 they commenced again with Shorthorns, raising annually one-fifth of the calves from the best cows. In this way the stock has been improved so that a good flow of milk is obtained.

After remarking that the ranch at Point Reyes was broken up into numerous hills and valleys, some of the hills almost approaching the dignity of mountains, Mr. Willard mentions the following to show that the size of the stock may be influenced by the surface of the country. He says: "This uneven surface, requiring climbing of hills and descent into valleys in quest of food, has had a strongly marked influence on the size and form of the stock. The animals are quite small for Shorthorns, and apparently more active than is usual with that breed, showing, in a very marked degree, what a controlling influence the surface of a country has in moulding the form of animals. The stock we found universally in fine condition as to flesh, and in every respect appeared to be in vigorous health; but the smallness in size was a point of interest to us, as showing how animals bred for several generations in a hilly country gradually adapt themselves to the surface over which they are compelled to travel in quest of food."—*Newport (Vt.) Express.*

Roots for Milch Cows.

In a recent number of the *Mark Lane Express* we find a statement from an English writer on the comparative value of mangels, carrots and turnips, for the production of milk. He regards both the carrot and mangel as inferior to the turnip, when quality of milk is sought—that is, milk abounding in cream. He says:—

"Although mangel-wurzel enables cows to give a large supply of milk, it is of a poorer quality than when they are turnip-fed, and not nearly so productive of cream. The butter made from it has also a slightly acrid taste, not so powerful as that of turnips, perhaps, but much more difficult wholly to remove or even to obviate to a passable degree. The thinness of the milk, when wholly mangel-fed, and this unpleasant taste, make it imperative to feed with bran, grains, crushed oorn, or a portion of cake, during the whole time this root is being used with milch cows.

"Farm horses eat it with great apparent relish, and thrive well upon it; and by its use a moderate saving in oats can be effected. When grated and mixed with chopped hay, a very agreeable and appetizing mess is formed, both filling and nourishing, and highly conducive to the health of the animals. If grating is objected to on the score of extra trouble, the whole roots thrown into the feeding box with the cut hay do almost equally well, the saliva of the horse and abundant sap of the root itself moistening the chaff abundantly.

"In giving carrots to milch cows, the only recommendation they have is the absence of all unpleasant taste in the butter, as the milk is neither so abundant in quantity nor so rich in quality as that obtained in turnip feeding."

He remarks further that, some years ago, a series of experiments was instituted with different roots, the whole extending over a period of about four months, and the conclusion arrived at, after such a lengthened trial, was exactly that which is here recorded. But as a feed for farm horses they are recommended, as they save corn and give a fine gloss to the skin, besides keeping the animals in good condition. From 14 to 21 pounds in a single feed are a liberal allowance; anything over that being apt to affect the kidneys and induce excessive staling.

We understand that X. A. Willard has an engagement to deliver a series of lectures at Cornell University, this winter, on dairy farming.

Milch cows should be kept in good, not fat condition, and a few weeks before calving should be scrimped in their food. This especially with good milkers. By lessening the amount of blood in the cow there will be less milk secreted, and less straining or inflammation of the bag. The milk fever may thust o a great extent be avoided.

Keep Milking.—The practice of milking but once each day, says *Hearth and Home*, where cows give but little, late in the year, is a bad one. They shrink much faster, and if young, the habit of not "holding out" is formed, to the owner's subsequent cost. They should be milked, as long as they are milked at all, twice each day.

X. A. Willard gives it as his opiniou that hundreds of thousands of pounds of cheese have been lost during the last summer by the lack of attention to the temperature of curing rooms. He believes progress has been made during the past few years in this department, but much remains to be accomplished, and the principal improvement must lie in securing a proper and uniform temperature o the cheese while curing.

Colouring Butter and Cheese.—This was the subject of a paper recently read by Hon. H. Lewis, before the Little Falls Farmers' Club, and of a discussion which as usual followed the opening paper. Mr. Lewis was strongly opposed to the use of any artificial colouring, and presented a report by Professor Caldwell, showing that several samples of annatto submitted to him for analysis contained poisonous matter, chiefly salts of copper. Mr. Willard contended that pure annatto was not injurious, and that the fancy of consumers required the addition of some colouring adjunct, and justified its use by the manufacturer. A new article, under the name of anattoine, was now being introduced, which he believed to be perfectly harmless.

Entomology.

The Grape-vine Flea-beetle.

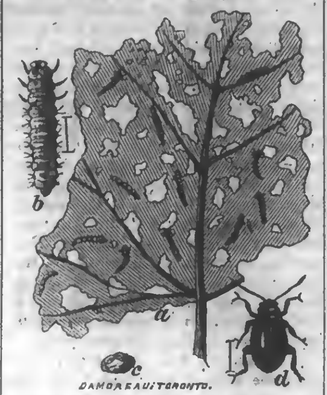
(*Haltica chalybea*, Illiger.)

Is there a grape-grower in the United States who does not know, to his sorrow, what the Grape-vine Flea-beetle is? Hardly one! And yet how few ever connect it with its disgusting little shiny brown larvæ, which generally prove still more injurious than the beetle, by riddling the leaves in the middle of summer.

The Grape-vine Flea-beetle often goes by the cognomon of "Steel-blue Beetle," and is even dubbed "Thrips" by some vineyardists. The latter term, as most of our readers are well aware, is entirely inapplicable.* The former name is not sufficiently characteristic, because the colour varies from steel-blue to metallic-green and purple, and because there are many other flea-beetles to which it would equally apply.

The Grape-vine Flea-beetle is found in all parts of the United States and in the Canadas, and it habitually feeds on the Alder (*Alnus serrulata*), as well as upon the wild and cultivated Grape-vine. Its depredations seem first to have been noticed in 1831, by Judge Darling, of Connecticut, and in 1834 Mr. David Thomas, of New York, published an account of it in the 26th volume of Silliman's *American Journal of Science*. Its transformations were, however, unknown till some time after Dr. Harris wrote his excellent work on Injurious Insects, and no figure of the larvæ has been hitherto published.

The beetles hibernate in a torpid state under any shelter which is afforded them in the vineyard, such as the loose bark and crevices of stakes, etc., etc., and they are roused to activity quite early in the spring. The greatest damage is done by them at this early season, for they often bore into and scoop out the unopened bud, and thus blight the grape-grower's bright expectations. As the leaves expand, the little jumping rascals feed on the leaves, and soon pair and deposit their small orange eggs in clusters, very much as in the case of the colorado potato beetle. These eggs soon hatch into dark-coloured larvæ, which may be found of all sizes during the latter part of May and early part of June. They are generally found on the upper surface of the leaf, which they riddle and devour. When very numerous they devour all but the very largest leaf-ribs, and we have seen the wild vines throughout whole strips of country rendered most unsightly by the utter denudation which these insects had wrought. The larvæ feed for nearly a month. They then descend from the vine and bury themselves a short distance in the earth, where, after each forming a little earthen cell, they change to pupæ of a deep dull yellow colour, and in about three weeks more issue as beetles. These beetles leave the ground from the middle of June to the middle of July, and, so far as we are aware, do not breed again till the following spring—there being but one brood each year. They subsist on the leaves during the fall, but the damage they inflict is trifling compared to that which they cause in spring.



The accompanying illustration represents this beetle in its various stages, and also the riddled and jagged appearance (*a*) of the leaf on which they feed. *b* is a magnified view of the full-grown larva, the natural size being indicated by the hair-line at the side. *c* represents the small earthen cell of the pupa, and *d* the mature beetle magnified, the true size shown by the hair-line.

Like all other flea-beetles, this species has very stout, swollen hind thighs. By means of these strong thighs they are enabled to jump about very energetically, and are consequently very difficult to manage during the summer months. In the winter time, however, they can be destroyed in great numbers while hidden in a torpid state in their retreats. Clean culture and general cleanliness in the vineyard will, to a great extent, prevent this insect's increase. Dr. Hull, of Alton, Ills., tells us that they were once so numerous in a small vineyard of his, that in the spring of 1867 he burnt them out by surrounding them with fire, and letting the fire run through the dry grass in the vineyard. "It was a rough remedy, but as his crop was destroyed, he let the beetles follow suit."

The larvæ can be more easily destroyed by an application of dry lime, used with a common sand-blower or bellows. This has been found to be more effectual than either lye or soap-suds, and is withal the safest, as lye, if used too strong, will injure the leaves.

This insect, like so many others, will one year swarm prodigiously, and then again be scarcely noticed; and such changes in numbers depend mainly on conditions of the weather, as we know of no parasite which attacks it. In the spring of 1868, though they were at first out in full force, yet after some subsequent severe and cold weather, they had mostly disappeared. They are apt to be most troublesome where alder abounds in the woods.—*American Entomologist.*

* The term *Thrips* is confined to an anomalous group of insects—mostly cannibal, but exceptionally vegetable feeding—of which Halliday made a separate Order (*Trysanoptera*), but which are to-day included in the *Homoptera*, or Whole-winged Bugs, by most authors, though they seem to have close affinities to the *Orthoptera*, and to the *Pseudoneuroptera*

The Poisonous(?) Tomato Worm.

To the Editor.

Sir,—In your issue of 15th October, which a friend has just placed in my hand, I have read your article under the above heading.

No doubt a fair criticism of such a subject falls within the scope of your duties. But I ask, have you a right as a gentleman, however retired within the Editorial *Sanctum Sanctorum*, to make such reflections upon any inhabitant of Dundas as your article contains—without at least first learning either the facts of the case or his habits of life? And this too, after my name had been so freely mentioned in the recent paragraph in the newspapers you refer to. I assure you the paragraph or any newspaper mention of the matter was not of my seeking, or to my liking; nor was it strictly according to the truth of the singular occurrence.

Why your mind revels in pouring "spirits down to keep spirits up" I cannot imagine, because there is no such statement in the paragraph in question, as it only states the application of tobacco steeped in whiskey as a poultice to the wounded parts; and you do not hesitate to add, for sensational writing, another circumstance to such paragraph, namely, "He sent a swift messenger for the doctor," which, however cleverly written, is purely your own invention.

Now, although not so heroic as to thrust the "poisonous spines" of any insect into my fingers, as you say you have done in order to try its powers, yet all my neighbours will inform you—if you care to know—that I am about one of the healthiest and hardest subjects to be affected by poisonous matter, and am in no way inclined to "erysipelas," or to "get my arm into a sling," like your acquaintance you mention. I can assure you I have gone among cholera subjects and mosquitoes, without suffering more than you appear to have done from your experimental exploits in spiny science.

I can also assure you that no one acquainted with me will give you my character as a man accustomed to imbibe too freely; no, not even upon the excuse of the "Venomous beast," as you call the tomato worm.

Now, sir, if you think because you mention no name, that your article is a fair one, you must have forgotten that this tomato worm case has singularly become one of most annoying notoriety, owing to that

mighty engine of knowledge, "the Press," and as I have stated above quite against my will and without any act or part or even knowledge, until too late to prevent its publication; in fact, that it was published in the first instance only from information got through my children and their young friends, so far as I can learn.

I am, sir, your obedient servant,

"THE MAN OF DUNDAS."

Dundas, Nov. 23rd, 1870.

NOTE BY THE ENTOMOLOGICAL EDITOR.—From the above communication it appears that we have unintentionally wounded the feelings of "The Man of Dundas," by our recent article on the supposed poisonous Tomato Worm. This we regret very much, as our object was, not in any way to be personal, but to cast as much ridicule as possible upon the popular error of ascribing venemous qualities to this much maligned caterpillar. We have so often endeavoured in the columns of THE CANADA FARMER to disabuse the minds of the people of this country of their terror of this creature, and apparently to so little purpose, that we at once seized upon the little paragraph that went the rounds of the papers respecting the case at Dundas, as a fitting text for another article. We can assure our correspondent that we could have had no reference to his habits or mode of life, since to this hour we do not even know his name, much less are we acquainted with his private character. We merely inferred, both from the account of the case and from the popular and we believe proper treatment in such emergencies, that an unusual dose of spirits had been taken as a remedy. We wish very much that he had preserved the specimen which appears to have so much affected him, and sent it for identification to us or to some other entomologist. We are really most anxious to find out what ground there is, if any, for all the wonderful stories we hear regarding this poor unfortunate insect. For another article on the subject we may refer our readers, and our correspondent in particular, to THE CANADA FARMER for October 15, 1869, page 378.

THE RAPE BUTTERFLY, OUR NEW CABBAGE PEST.—This most destructive insect is fully realizing our prophesies. Salt is the common remedy, but Mr. Quinn, at a late meeting of the N. Y. Institute Farmers' Club, gave his experience as follows:—"I have tried no less than fifteen different powders and decoctions, and find the best result from the application of a mixture composed of twenty parts sulphate of lime, one part carbolic powder, and three or four parts of quicklime. This I sprinkle in small quantities upon the leaves and parts affected, making the application in early morning before the dew is off, or after a shower. Frequent repetition is sometimes necessary."

Correspondence.

Preserving Woodlands.

To the Editor.

SIR,—I noticed the other day an excellent suggestion in the address of the President at the late successful Fair at London, viz., that farmers should begin to plant trees for fire-wood, and he suggested the white willow as a good one for that purpose. I fear, however, that in a country like this, where labour is so expensive and the means of farmers so limited, few will act upon his excellent suggestion. But where farmers have a fair proportion of their farms in "bush," they can secure fire-wood for their own use and their descendants for generation after generation. A friend of mine John M. Ball, Esq., of Niagara, has not allowed his cattle, or horses, or sheep, to run in his "bush" for many years past; and he told me recently, that thousand and thousands of young trees are growing up in his bush, to the height of ten and twenty feet, which will replace those trees that will be cut down, when they cease growing, for the use of the house. In this way he expects, and I think with reason, that his "bush" will be continually replenished, as the seeds of the old trees strike root and send up young ones every year.

It is true, Mr. Ball loses a little pastnre about the skirts of his "bush," but that loss is nothing to what he gains by keeping his animals out of his bush, who would destroy the young shoots by browsing, if he allowed them, as most farmers do, the run of it. I might say that Mr. Ball mentioned his plan to me several years ago; and when travelling through the country, I have often regretted that the fine wood lots which I passed, and which were evidently growing thinner and thinner every year, had not been treated as Mr. Ball's have been.

I have often thought of writing to the public papers on the subject, but did not like to do so, until I had learned from Mr. Ball how his plan worked. Having now obtained full information on the subject, I feel it my duty to give it to the public; for, though it may be somewhat out of my line to write on such a subject, yet I believe it to be the duty of every patriot to do what he can to benefit his country.

The preservation of timber is well known to have a beneficial climatic influence, by drawing down more rain from the sky, as proved most incontrovertibly by the late very extensive experiments in planting trees, by the Pasha of Egypt; and as we suffer most years from excessive droughts in Ontario, it should be the object of all farmers to secure more moisture by maintaining as great an extent of forest as possible in the country. I trust that those farmers who can do so, will follow the excellent example of Mr. Ball. T. B. FULLER.

Toronto, Oct. 3, 1870.

Working Cows.

To the Editor.

SIR,—A few years ago I read in some agricultural paper of a man who had trained a pair of cows to plough and do other farm work; and so far from spoiling them for dairy purposes, he said they gave more milk than any other two cows he had. Not that the working made them milk better, but the extra care and feed they got on account of the work told on the milk. Would you state, for the information of a reader of your valuable journal, whether in your opinion such a plan would be practicable, and would it be worth while for one near a cheese factory, with a small quantity of arable land, to make the experiment? J. M.

Bridgewater.

NOTE.—With a *small* quantity of land, entailing only light work, the experiment might be made; but heavy work would be apt to tell injuriously on the secretion of milk.

The Cattle-fly Disease.

Notwithstanding the investigations that have been made during the past summer into the nature and causes of the so-called "fly disease," by veterinarians and entomologists, there still seems to my mind some doubt on one or two points which require further elucidation. Why, for instance, has the complaint been so much more severe during the past season? If the fly be the sole cause, have we not had the fly from time immemorial, and yet it never gave a tithe of the trouble that we have experienced this year. One thing, however, and that the most important, seems to have been established, and that is the efficacy of tar in various preparations to keep off the pest and heal the sores.

A curious fact in connection with the matter has come under my notice, namely, that these flies which have tormented cattle and horses so during the past summer seem to shun particular places. Cattle kept in dark stables during the day, and turned out to graze in the night, are free in a great measure from the torment, and when soiled during the day in the stable in the dark, and turned out at night, take no harm.

In the township of Bosanquet, at the upper turn of the River Sable, there is a long wooden bridge about twenty feet high above the water, and defended with the usual protection on each side. This bridge, or rather the middle of it, seemed to have an immunity against the attacks of the flies, and the cattle and horses soon found it out. The consequence was that they crowded the bridge, and remained on it during the day-time, until the dung of the animals had accumulated to more than a foot deep, and it seems likely to destroy the timbers by the decay it will induce, for its being nobody's

1871.) PROSPECTUS (1871:

OF

THE WEEKLY GLOBE.

THE GLOBE PRINTING COMPANY gratefully acknowledge the support extended to their several publications throughout the length and breadth of Canada during the past year, and especially to THE WEEKLY GLOBE. Twenty-seven years have rolled by since the establishment of THE GLOBE in Toronto. From its first appearance to the present hour its prosperity and influence have been always advancing; but at no time has it ever before held so firmly, or so satisfactorily, the position universally conceded to it, as the leading newspaper of British America.

The improvements recently made on THE WEEKLY GLOBE have immensely extended its popularity and circulation; and the publishers confidently claim that it is not only the most widely circulated Journal in British America, but that it is

The Largest, the Handsomest, the most Carefully Conducted,

AND THE

Cheapest Weekly Paper on this Continent.

During the coming year—which is likely to bring with it important events affecting the political and material interests of the Dominion—the Editorial and News Departments will continue to be sustained with the ability and vigour that have gained for the paper its present position. A reliable summary of the Debates in the Dominion Parliament and the Provincial Legislatures will always be found in its weekly columns; and the news from all parts of the world will be published up to the latest hour of publication.

THE GLOBE will continue to advocate with all energy, as heretofore, ECONOMY IN EVERY DEPARTMENT OF THE PUBLIC SERVICE—a generous system of immigration—the rapid settlement of our wild lands—the prompt opening up of the great North-western Territories—the vigorous development of our fisheries, and of the mineral and agricultural resources of our country,—and the removal of all obstacles tending to retard the progress of industrial and manufacturing enterprises. It will continue to strive earnestly for the improvement of inland navigation, the adoption of a well-matured Homestead Law, and the throwing open of the wild lands of the country FREE to actual settlers. It will continue to cultivate the most friendly relations with the neighbouring Republic; and will hail with pleasure a new Reciprocity Treaty, but only on terms fair and honourable to both countries.

THE AGRICULTURAL DEPARTMENT,

That has given such universal satisfaction this year—and that is acknowledged by every farmer to be alone worth the subscription price of the paper—will be maintained in 1871 with undiminished interest, under a still more efficient staff of editors and correspondents than before.

SEVERAL NEW AND EXCITING TALES,

From the pens of popular authors, will appear during the year. No expense will be spared in securing the very latest intelligence by means of **Special Telegraph Dispatches, Market Reports, Prices Current, and General Commercial Intelligence,** from all parts of the world, will receive unremitting attention. Every department of the paper will be maintained in the highest state of efficiency.

Notwithstanding the great enlargement and improvement of the WEEKLY GLOBE that have recently been made, the subscription will continue to be only

TWO DOLLARS PER ANNUM,

Payable always in advance—and the following will be the

Club Rates for 1871.

A Club of Five Copies, one year			$ 9 00
Do.	Ten	do.	17 00
Do.	Twenty	do.	32 00
Do.	Thirty	do.	45 00

And each additional copy over thirty, at $1.50.

LARGE PRIZES

Are given to parties who get up Clubs, a list of which will be sent to any one who will apply for it by letter or personally at the Office. Any one is at liberty to get up a Club on his own responsibility; and those desiring to do so should send at once for a Circular showing the terms.

Club Agents can send in names from time to time as they receive them, and their Prizes will of course be determined by the numbers they ultimately make up.

To facilitate the work of Canvassers, all parties subscribing (in a Club or otherwise) between 1st December, 1870, and 1st January, 1871, will have the paper sent to them up to 31st December, 1871, on payment of a year's subscription.

Payment must always be in advance. No paper sent from the office until the cash has been paid.

Each paper shall be addressed separately, and may be for any Post Office.

Orders and Remittances to be addressed to

The Globe Printing Company, Toronto.

1871 PROSPECTUS 1871

OF

THE CANADA FARMER.

OFFICE EDITOR—J. E. ELLIS, Esq., M. R. C. S., England.
HORTICULTURAL EDITOR—D. W. BEADLE, Esq., St. Catharines.
SPECIAL CONTRIBUTORS—Professor BUCKLAND, E. L. CULL, Esq., J. A. CULL, Esq., C. E. WHITCOMBE, Esq., M.R.A.C., England.
DRAINAGE EDITOR—ALAN MACDOUGALL, Esq.
ARCHITECTURAL EDITOR—JAMES SMITH, Esq., A. M.
ENTOMOLOGICAL EDITOR—REV. C. J. S. BETHUNE.
VETERINARY EDITOR—ANDREW SMITH, Esq., V. S. Edin.
APIARIAL EDITOR—J. H. THOMAS, Esq., Brooklin.

The conductors of THE CANADA FARMER will continue to labour earnestly for the following ends:—

To arouse attention, by frank and temperate discussions, to all questions, scientific, commercial, legislative or otherwise, specially affecting the farming interests.

To stimulate the agriculturists of our country to adopt an improved system of husbandry, by blending the lessons of modern science with the practical experience of the Canadian farmer.

To bring under the attention of our farmers all improvements at home and abroad, worthy of adoption, affecting the management of Field Crops—the Barn Yard—the Stable—the Dairy—the Orchard—the Poultry Yard—the Apiary—the Kitchen Garden—and the Flower Garden; and to excite an interest in the progress of Rural Architecture and Landscape Gardening, and all that concerns the domestic economy of the Farm House.

To mark and report all improvements in Agricultural Machinery, foster new inventions, and promote the adoption of all labour-saving machines, in the work of the farm and garden.

To keep prominently under attention all that specially concerns the Dairy Farmer and the Grazier—the best breeds of Cattle—the best systems of feeding—the most approved processes of cheese and butter making—the best mode of packing—and the best markets to sell in.

To keep prominently in view whatever is specially interesting to the Sheep-raiser and Wool-grower—the breeds best adapted to our climate—the best system of winter and summer management—and the varying prospects of the wool market.

To afford the Farmers of Canada an ever-open medium for addressing their brother Agriculturists throughout the Dominion, suggesting matters of common interest and advantage, and eliciting information or advice on practical questions of difficulty or doubt.

To report concisely the proceedings at Agricultural Shows, Fairs, and Sales, throughout the Provinces—note the condition and progress of the Herds and Flocks of prominent Stock-breeders; and record the importation of Thorough-bred Stock from abroad.

To watch and report carefully and promptly the actual state and probable prospects of the Produce markets, at home and abroad; and specially promote all movements designed to secure the best prices in the best markets for Canadian Farm Produce.

To afford the Farmers of the Dominion a common medium, where all who have for sale Live Stock, or Seed, Grain or Land, or who may wish to buy such, can make their desires known directly to the whole farming population of Canada.

THE CANADA FARMER will continue to be issued on the fifteenth day of each month,—the form will be the same as now—and each number will contain

FORTY PAGES OF READING MATTER.

The Price will continue, as heretofore,

ONE DOLLAR PER ANNUM, FREE OF POSTAGE.

CLUB RATES FOR 1871.

CLUB OF TEN COPIES	$ 9 00
CLUB OF TWENTY COPIES	16 00
CLUB OF THIRTY COPIES	22 50

☞ And all over 30 at 75 cents per copy.

Letters and remittances to be sent to

THE GLOBE PRINTING CO.,

TORONTO, ONT.

TORONTO, 1st Dec., 1870.

special business to keep it cleaned off, the final destruction of the bridge by decay seems imminent.

One old mare stuck to the bridge until she was nearly starved, rather than expose herself to the flies on the lower ground, and her owner had not only to drive her to her feed, but to keep her there.

The same observation has been made in regard to other high bridges, the centre of which has, during the fly season, been crowded with cattle, who persistently returned to their station even after they were driven away.

VECTIS.

Beet Sugar Making.

A correspondent from Brighton writes:—"As I intend to establish a sugar beet refinery, I would like to enquire if there is any sugar beet refinery in the Dominion, or in the United States, where I could learn the business of refining."

The only sugar beet factory to which we can direct our correspondent is that at Chatsworth, Illinois, U.S. This, we believe, is the only one that has been in operation, for some years, but we warn our correspondent that there has been more progress made in the knowledge of the various ways of making sugar from beet root, during the last four years, than in any previous ten. Science and chemistry are at work, and have been actively called into operation by the remunerative profits of the business in England, and it is more than probable that any old-fashioned factory may be far behind the age and time. We do not know that there may not be many modern improvements here also, but we have heard that the enterprise as conducted at Chatsworth does not pay; but this *may* depend, and probably does in part, on the difference between beets grown on prairie land and elsewhere.

TEETH A TEST OF AGE.—"Subscriber" asks, "Is it uncommon for Merino shearling ewes to have four broad teeth? or, in other words, do cases occur in which Merino (or other sheep) have four broad teeth when only one shear?" The number and development of the teeth are among the surest and most constant marks of the age of any animal, but like all other signs, are liable to variation. Some animals grow faster and mature much earlier than the average of the same species, and all writers on the subject refer to exceptional instances in regard to the appearance of the teeth. Randall says, "There is sometimes a variation of a number of months or even a year in the development of the teeth. High kept and rapidly grown sheep acquire their second teeth much earlie."

MUSHROOMS.—J. M. asks "How is a mushroom distinguished from a toadstool? and is there any way of propagating the former?" The edible mushroom, when it is from eight to twelve hours old, has beautiful pink or flesh-coloured gills—that is, the under side of the crown is of that colour, and has a fresh sweet smell. As it gets older, these gills turn chocolate colour, and finally almost black. The appearance then more nearly approximates to that of some poisonous fungi. But the place of growth may assist in distinguishing them. Mushrooms grow in pastures or meadows, the fungi resembling them in woods, and these have besides an unpleasant sickly odour. The following test is also, we believe, correct. If you sprinkle a little salt on the gills, and they turn yellow soon after, these should not be eaten; if they turn black, they may safely be eaten. Our correspondent will find directions for artificially growing mushrooms in the September and December numbers of the CANADA FARMER for 1869.

WESTERN WHEAT.—A correspondent asks, "Can you or any of your readers inform me whether the Milwaukie or Kansas wheat, now being largely imported by our millers, would be a safe seed for Canadian soil?" We have not seen any of this wheat, but should suppose it was of a very mixed kind, not adapted for seed. Perhaps some of our readers can give information on the matter.

The Canada Farmer.

TORONTO, CANADA, DEC. 15, 1870.

The Volume for 1870.

The present number of the CANADA FARMER will complete the second volume of the new series, and the seventh since its commencement in 1864. It has been the aim of all connected with its publication to promote the important objects for which it was established, by taking note of the general progress of agriculture and kindred departments of industry, and by affording to Canadian agriculturists a medium of intercourse with one another, for discussing subjects of common interest, and comparing the results of their experience. Above all, we have endeavoured to impress the farmer with a higher sense of the dignity of his calling, and so to elevate it from a mere mechanical toil to a science, in which there is ample scope for the energies of the mind, as well as the exercise of manual labour and skill. How far these objects have been attained it is for our readers to pronounce. We have reason to be gratified and encouraged by the continued interest manifested, the increasing circulation of the journal, and the evidences of appreciation and approval in the contemporary agricultural press both of this continent and of Great Britain.

In the volume now completed, among other features of interest, special prominence has been given to the cultivation of the Beet and the manufacture of Beet Sugar, because this industry has not only for many years exerted an ameliorating influence on Continental agriculture, but has been introduced with marked success into Great Britain, where, within the last year or two, immense improvements have been effected in the processes of manufacture, and we are desirous of seeing a fair experiment made in Canada, believing that there is nothing in the character of our soil, or climate, or market, to prevent the success of such an enterprise.

Attention has also been directed to the great progress manifested during the past year in the improvement of live stock; particularly in the breed of Short-horn cattle. Numerous and valuable importations have been made, a large proportion of intelligent farmers are practically recognizing the value of pure blood, and the number of choice herds and flocks now owned by Canadian breeders, cannot fail to raise the general character of live stock throughout the country.

In the coming year we shall keep these and other subjects of like importance steadily in view; and no pains will be spared to render the CANADA FARMER acceptable to our subscribers. We cordially invite their co-operation, and hope to number among them many new friends.

The terms for Agricultural Societies and Clubs, as published elsewhere in the prospectus for 1871, will continue on the same liberal scale as heretofore.

Farmers' Clubs.

Now that the long winter evenings are coming, and the farmer, having shorter working hours, can give time and attention to the endeavors to gain or impart information in regard to matters connected with his calling, every effort should be made to organize and keep up a Farmers' Club in each ward of a township, or each considerable village having a good farming country adjoining it. The school-room of the ward would be a good place at which to meet. If that cannot be had, let the members take turns in gathering at each others' houses once or twice a week. We have already given in times past an outline of the mode of proceedings to be adopted in organising and carrying out a farmers' club, and in fact, they may as well be made as free from rules and regulations as possible, so that each one will feel under no restraint, but be at liberty to come forward and speak on whatever topic is brought under discussion by the one who is in the chair for the evening. Don't talk all at once, or keep up a general conversation in quiet corners with one another, but let everything that is said be directed towards the general enlightenment of the club, and be listened to with respect; and when one speaker has sat down, a short interval may occur for general discussion before the next is called on to address the meet-

ing on the subject brought forward. Such a club can be made of great benefit to a neighbourhood in many ways. Among others, they can put each other on their guard against any patent right swindler, and tricksters of every sort who may come into the neighbourhood, and who often succeed in their designs through falsely using the name of one neighbour to another as having purchased, or subscribed for their worthless trash. They can also gain much information from one another's experience in growing new sorts of grain, breeding and feeding stock, and the practical working of implements of husbandry of different patterns. When the club becomes large and influential it may prove both useful and desirable to have a secretary to report discussions, and forward notes of the most important ones to the local paper of the district, or the agricultural press.

Let the thing be tried, and persevered in, and by means of so simple and inexpensive a course of procedure, it will be found that a vast amount of practically useful information might be given to the country.

Re-organizing Farm Life.

One of the very best and most practical addresses ever delivered was given by Prof. A. A. Hopkins, of Rochester, N. Y., before the people at the Western New York Fair. From it we make a few somewhat lengthy extracts which ought to be read and acted upon by every farmer throughout the land.

"*Farmers' homes are boarding-houses for hired help, and Farmers' wives are almost bond-women. The larger the farm, the worse the servitude.*"

"Look about you, everywhere, and see if the facts do not corroborate this statement. 'Boarding-houses for hired help' accurately describes the generality of farmers' homes. On a farm of two hundred acres, more or less, there are usually two or three labourers by the month, and as many more by the day, perhaps, in the busiest season. These, as a rule, board with their employer. That his wife is almost a bond-woman follows, as a matter of course.

"How can she well be otherwise? From March to December any way—very likely the whole year round—there is the hired help tying her at home. Her good man goes off the farm every day nearly—to the mill or the post-office—and feels a lessening of the burden in social intercourse with his fellows; she labours on, day in and day out, week in and week out, fortunate even if she get to church on a Sunday; the hardest worked person in the whole family; the one whose abour is never done; the one whose toil has smallest compensation.

"There is no sadder picture anywhere than some farmers' wives I have seen. The look of *weariness* on their faces is eloquent of sighs—sighs for a happy girlhood gone, for a life with somewhat in it sweeter than drudgery. Do they complain? Rarely, to their husbands. They are good wives, as the term goes; they accept their burden, and bear it bravely as they may, with no loud-voiced lamentings.

"We whose work is for the public, and whose duty it is to help right every wrong, get letters from them, sometimes, that are full of the heartache. They write to us what they seldom give utterance to otherwise—their discouragement, almost their despair.

"They tell us how, in the years intervening since their marriage morn, Toil and his twin-brother Care have held them captive continually; how their husbands, by constant contact with the outer world, have grown into a broader life, while theirs has narrowed down to the kitchen's confines; how they feel themselves becoming a less and less fractiou of the married unit, instead of keeping even growth with their companions; how they long for a wider outreach, and a nobler, more satisfying life.

"And these are not the women whose desired broadening of being takes in the pulpit, the platform, or the polls. Their aspirations are not of that character, at all. What they do wish, what their patient long-suffering should entitle them to, is such a reorganization of the home-life as will give them some leisure for personal comfort, personal culture, and personal growth.

"'Is it possible?' comes the question. It is proved so, in many instances. 'I have always boarded my help until the present season,' said a farmer to me early this summer, 'but I shall never do it again. I built a tenant house yonder,' and he pointed to a neat little domicile twenty rods from his own, 'and it has paid its cost already in the added privacy and quiet it has enabled me to enjoy, and in the great lessening of work for the women folks.'

"Tenant houses will pay their cost always—will pay it directly, in dollars and cents, in the long run; will pay it indirectly, in the manner my friend indicated, within the first year. Every farm, large enough to require help the season through, should possess one.

"It is not quite clear to me that woman's millenium is coming through the ballot, but I am morally certain that something very like a millenium will come to many women by the general erection of homes for hired help. The good time is coming, ladies; you must call upon your husbands to fix the date!

"I preach the sweet gospel of Hope to every troubled matron who, like Martha of old, is cumbered with much serving, and bid her take heart again. There is to be somewhat besides 'eternal dishwashing' in your future—somewhat besides the never-ending round of washing, baking, churning, ironing, mending, and the like. It may not be the suffrage—I almost hope it will not, for your sake, and for our sakes, to whom Ruth is the sweetest type of womanhood, and who would have you remain a Ruth for ever—but it will be a somewhat better than suffrage, be that never so good. It will keep the light in your eyes and the love in your hearts, and under its kindly influence you shall grow younger, as the years go on, until, a happy girl once more, you sit beside your Boaz on life's harvest eve, glad with abundant gleaning, grateful for your being and its fruits, your home a pleasant foretaste of that heaven beyond the twilight.

"Such a reorganization of home-life on the farm as I could wish wrought out would comprehend much more than the building of tenant houses. While that might be the initial step in many cases, the work would extend further by far, and would touch very nearly the home's centre."

Diseases of the American Horse.

A new work, under this title, has been issued by R. McClure, V.S. It is a small octavo of over 400 pages, and contains in concise form a large amount of valuable information on the nature and treatment of equine ailments. There is also a short account of cattle diseases, and a brief notice of some of the more common disorders affecting sheep. The arrangement of the subject is novel, the various topics being taken up in alphabetical order, without any regard to their relations. We do not admire this feature of the work. An index of reference would have served all the useful purposes of such an allocation, without violating all the mutual bearings of diseases and their organs. The author is, however, well acquainted with his subject, and fully qualified to give instruction. The descriptions and directions are plain and brief, and the treatment recommended sound and practical. The work is published by John E. Potter & Co., Philadelphia.

Constitution and Bylaws of a Farmers' Club.

We have often received applications from Secretaries of Agricultural Societies and others, to furnish some guide or instructions for framing the rules of a farmers' club, and have replied to such correspondents that no special rules were necessary, that the organization was of the simplest, and that the circumstances of the locality would suggest the most feasible methods of carrying on the institution. The following specimen of the rules of a Farmers' Club actually in operation may, however, be of service to those about to form such a society. There is nothing worthy of note about them, and each club will make modifications from any set form to suit all its own requirements; and we publish these only because we have so often been consulted on the subject, and the following simple form may be a guide to the inexperienced in such matters:—

CONSTITUTION.

I. This organization shall be known as the ——— Farmers' Club.

II. Its object shall be the improvement of the members in the theory and practice of agriculture, and the dissemination of knowledge relative to rural and household affairs.

III. Its members shall consist of such persons as shall sign the constitution and by-laws, and pay annually the sum of ———

IV. Its officers shall consist of a President, (two) Vice-Presidents, Secretary and Treasurer, who shall jointly constitute the Executive Committee, and shall be elected annually.

V. Its meetings shall be held weekly, (fortnightly, or as the case may be), at such places as may be designated by the Club.

VI. This constitution may be amended at any regular meeting by a majority of the members present, said amendment having been proposed at the previous meeting.

BY-LAWS.

I. The President shall preside at all meetings of the Club and Executive Committee, and have power to call special meetings.

II. One of the Vice-Presidents shall perform the duties of the President during his absence.

III. The Secretary shall record the proceedings of the Club and conduct its correspondence.

IV. The Treasurer shall receive all moneys, and pay the same on the written order of the President, countersigned by the Secretary.

Report of the U S. Commissioners of Agriculture for 1869.

We have received from the Hon. Horace Capron, Commissioner of Agriculture for the United States, a copy of the report of the Agricultural Department for the year 1869. Though issued somewhat late, the volume nevertheless contains so much matter of permanent interest that it will prove a valuable acquisition to any agricultural library. The compilation presents some features of novelty, as compared with similar reports in previous years, and is in many respects a decided improvement upon them. Besides the general summary of the Commissioner himself, there are other valuable reports from the statistician, the entomologist, the chemist, the botanist, the superintendent of gardens and grounds, and an elaborate paper on agricultural meteorology, by Andre Poey, which will well repay an attentive study. In the place of the usual essays or monographs of former years, the editor, J. R. Dodge, has compiled a number of interesting papers on some of the most important subjects connected with agriculture and horticulture. We may instance Landscape Gardening, Fruits, Seeds, Steam Culture, Beet Root Sugar, American Dairying, and a number of other equally interesting matters. From some of these valuable articles we hope, at a future time, to draw largely for the information of our Canadian readers. The work is illustrated with a number of engravings, which add to the intrinsic value no less than the attractive appearance of the volume.

Report of the Michigan Board of Agriculture for 1869.

The eighth annual report of the Michigan Board of Agriculture for 1869, a copy of which we have received from the Secretary, Sanford Howard, contains, besides an account of the Michigan State Agricultural Society, a report of the Michigan Agricultural College, and notices of some interesting experiments conducted by this valuable institution, and some admirable essays which have excited prominent attention during the year, such as a paper on wheat and its cultivation by the Hon. Geo. Geddes, European Agriculture, by Mr. James Howard, the prize essay on cheese, by Mr. Arnold, of Ithaca, Professor Law's paper on the feeding of cattle, a brief report by Messrs. Baker on cheese dairying, or the factory system, and a paper on long-woolled sheep. There is also appended a report of the Western Michigan Lake Shore Horticultural Association. Altogether, the volume is, as usual, full of valuable instruction of special interest to the agricultural reader.

Artificial Manures.

We notice by the report of the Chemical Committee of the Royal Agricultural Society on Adulterated Manures and Feeding Stuffs which has just come to hand, that the farming public of England is imposed upon to an extent far greater, so far as we can judge, than we in this country are. Professor Voelcker has been analyzing these vile compounds, sold often at high prices, and the composition and utterly worthless quality of some of them would be subject of amusement, were it not a matter of too serious importance to the farmer who buys. A sample of bone manure contained only one per cent. of phosphate of lime and one per cent. of nitrogen. It was made up chiefly of gypsum and some cheap organic refuse, impregnated with sulphuric acid. It cost four and a half pounds sterling per ton, and was worth less than a pound and a half. Other specimens were still worse. Carbonate of lime and fine sand were mixed in largely.

Now genuine bone dust or bone meal contains forty-eight per cent. of phosphate of lime, and yields four and a half per cent. of ammonia and no amount of sulphate of lime. All additions of the latter are cheats.

There is also a remarkable falling-off in the quality of recently imported Peruvian guano. It contains much rock or sand. The supply on the Chincha Islands is probably running rather short. The British farmer is terribly imposed upon in the article of commercial manures.

Editorial Notes.

During the first week of November, we visited some of the western counties, along the line of the Great Western Railway. Owing probably to the very mild favourable weather we have enjoyed this autumn, the work of gathering in the root crops had hardly yet commenced, and even in many orchards the apple trees were still loaded with their fruit. The Indian corn crop, so far as we could ascertain, is one of the best ever harvested in Canada, both as regards the quantity and quality, and the stalks have been saved in such excellent condition that with proper after-care they must form quite an item in the way of food for stock to many farmers, which is a matter of consequence owing to the somewhat short hay crop caused by the dryness of the early part of the summer. It will be well for those who have corn stalks on hand to endeavour to make the most of them, by cutting and steaming before feeding out to their cattle. The addition of a little barley or pea meal to the steamed mess will go a great way towards inducing the stock to eat it all up clean; and corn-stalks, if well saved, are much more nutritious than the best straw that can be had.

A large breadth of winter wheat appears to have been sown, and most of it is not only put into ground that is in capital order for the production of good wheat, but has been sown at an earlier date than usual, and owing to the favourable season the wheat plants appear to be remarkably strong and healthy, and the ground well covered. In fact, in some instances the wheat had attained somewhat too rank a growth and appeared thicker on the ground than there was any necessity for at so early a stage of its growth. With a favourable winter and enough of snow to prevent the destruction of this crop by severe frost, and a dry summer after, we may anticipate that the yield next year will be one of the heavisst ever gathered in Canada. The success of this crop during the past three years, since that once dreaded scourge, the wheat midge, has abated its ravages, has induced our farmers to be more careful in preparing their land, and hopeful of the results of their labours.

A short trip into Michigan showed a wonderful contrast between our neighbours' system of farming and ours. The absence of root crops was most marked, while the presence of so many undrained swamps and almost stagnant rivers showed evident cause for the general prevalence of ague and other malarious diseases that are the bane of the settler in those western wilds. The corn fields seemed, as compared with ours, to be but half cultivated, and several appeared to have a heavier crop of weeds than corn on the ground, the weeds in some instances overtopping the corn in height; and it was a marvel how the farmers there could allow them to ripen such a

heavy crop of foul seeds to spread over the land, and rob it of its riches.

The country over portions of western New York presented an agreeable contrast to the state of things in Michigan. Here we find well-cultivated farms, good buildings, and along the line of New York Central Railroad, for 100 miles eastward of the Falls of Niagara, a fine fruit region, with large orchards well loaded with the finest fruit. The operation of a new cattle law, prohibiting stock from running on the highways, has resulted in some farmers entirely removing their fences from the road-side; and as one consequence of the highways being no longer kept in order by the grazing of stock, they were fast becoming overgrown with weeds, which seemed to be allowed to ripen their seeds unchecked, and so form the nucleus for distributing foul weeds over the fields. This might be easily avoided, if it were made compulsory to destroy them before they blossomed, or by seeding down the road-sides to clover or timothy, and allowing the farmers to cut it as hay. It will come to this in time, when they find out the evil of the other course of allowing them to become the nursery for weeds. On the whole, wherever we went, we saw evidences of improvement in the system of cultivating the soil. Much of this is due to the introduction of better and labour-saving machinery on the farms; but still more, we think, to the wide circulation of agricultural journals, inducing more thoughtful care in the management of farms, more attention to the rotation of crops, and a more liberal expenditure of capital in manures and improvements, instead of hoarding it up at small interest in the banks.

The pleasantest experience we enjoyed during our trip was a short visit to Moreton Farm, near Rochester, N. Y., the residence of Joseph Harris, well known as the writer of "Walks and Talks" in the *American Agriculturist*. Six years ago he purchased at a cheap rate 285 acres of the poorest and most worn-out farm in Western New York. By means of under-draining and good cultivation he has brought this farm to be one of the richest and most productive in the state. It was originally covered with stones and boulders, the soil being naturally good, but in a sadly neglected condition. The boulders have been blasted out, the stones gathered up and made to do work as fences, there being already many dry stone walls built on the farm. The finest crops of clover, corn, and wheat are raised, and what was once a desert now blooms as a rose. This has all been accomplished more by good management, than any lavish expenditure of capital for artificial manures or high farming. Under-draining, deep ploughing, and growing clover to be fed off by sheep, have been the principal means used. Mr. Harris's flock of Cotswold sheep are of the finest quality as regards their wool we have ever seen. The lambs of this year are especially so, and they are being bred with the object of getting sheep that shall yield a fleece of the softest and finest combing wool it is possible to obtain. They are not kept up to the high condition of flesh our breeders usually admire, consequently do not attain heavy weights, but they are thrifty and healthy. The Essex pigs on the farm are the finest we ever saw of the breed, and some cross-bred spring pigs, by an Essex boar from a Berkshire sow, seem remarkable specimens of porcine thrift and beauty. They will go over 300lbs each by Christmas. Does the farm pay? Mr. Harris pays high wages, but gets the best men that can be had, and is quite satisfied that the farm not only pays well, but is the best investment he ever made. It has trebled in value since he bought it, and his crops are steadily increasing in yield every year. He has besides set such a good example to his neighbours that they are beginning to stir up and go and do likewise. The story of his doings on this farm, as given in "Walks and Talks," has done more to awaken an interest in the improvement of agriculture in the United States than anything ever yet written.

Notes on the Weather.

The mild Fall weather which characterized the early part of the season has continued throughout the month of November, and judging from one's agreeable impressions of the pleasant temperature, contrasted with the vivid recollections of the cold of last year during the corresponding month, one would be disposed to pronounce the November of the present year as exceptionally mild, if not warm. The records of the Observatory, however, would correct this idea, and show that the month, pleasant as it has been, can only claim an average character as regards temperature. Indeed, the mean has been a trifle below the average of the last thirty years. The amount of rain-fall or snow has been less than usual. Very little of the latter, except on one occasion, has fallen in the neighbourhood of Toronto, but in other districts west and east, as well as towards the north, where it would be earlier looked for, there has been a considerable fall and some sleighing. A more favourable season for maturing and harvesting root crops could not have been enjoyed, and we suppose such a thing as a lost turnip crop, from being frozen into the ground or covered with snow, will not be heard of this year in the Province.

The records of the Toronto Observatory already referred to show that the mean temperature of the month has been 36.6, which is 0.1 colder than the average, but 3° 9 warmer than the mean temperature of last November.

The highest temperature was 57° on the 2nd instant, which was also the warmest day, with a mean of 49° 6. The greatest degree of cold occurred on the 22nd, the mean temperature of which was 27° 4, and the lowest 19° 4.

Rain fell on six days to the total amount of 0.594 inch, being 2.576 less than the of 0.594 inches, being 2.576 less than the averages.

The total amount of snow was 3.1 inches, being slightly below the usual quantity, and as much as 7 inches below that of November, 1869. The first snow of the season fell on the 10th of the month.

There have been 5 clear days, 16 partially clouded, and 9 entirely so.

The prevailing winds have been from the west.

The Horticulturist.—This long established and excellent periodical maintains its reputation as one of the best horticultural authorities in the United States. It is well printed, beautifully illustrated, and full of useful practical instruction. The publisher is H. T. Williams, New York—the price $2per annum.

Mr. Gibb, of Compton, has again added to his fine herd of imported Ayrshires. The last arrivals of which we have heard consisted of Lady Avondale, who gained the first prize at the Highland Society show this year; May Bell, also the winner of several prizes; Mary, Miss Meikle, Blooming Daisy, and Heather Bell—all prize winners. Other cattle were on the way when these arrived, and have no doubt before this reached their destination. Mr. Gibb seems determined to introduce the best class of Ayrshires into the country.

Hearth and Home.—This deservedly popular agricultural and family periodical has passed from its late proprietors into the hands of the enterprising publishers, Orange Judd and Company, and is now issued from the office of the *American Agriculturist*. Its price is also reduced from $4 to $3 per annum (Am. currency.) It is conducted with spirit, admirably illustrated, and contains, besides agricultural and horticultural matter, a summary of news, popular tales, and other matter of general interest, making it a welcome family paper in rural districts.

Transactions of the Wisconsin State Agricultural Society for 1869.—Our acknowledgments are due to the Secretary of the Wisconsin State Agricultural Society for a copy of the report for the year 1869. The volume contains a brief account of the condition and progress of the State and the proceedings of the Society during the year, together with practical papers on agricultural matters by such eminent writers and practical authorities as X. A. Willard, J. D. Webb, and J. B. Lyman on dairy interests; Marshall P. Wilder on horticultural subjects, and others equally eminent on almost every branch of agriculture and rural economy.

Horticulture.

EDITOR—D. W. BEADLE,

CORRESPONDING MEMBER OF THE ROYAL HORTICULTURAL SOCIETY, ENGLAND.

Fruit Growing in the West Division of the Ontario District.

From the Report of the Fruit Growers' Association of Ontario for 1869.

The West Division of the Ontario District embraces the Counties of Peel, Wentworth and south part of Halton.

The following varieties of apple are recommended to be planted within this division, viz:—Autumn Strawberry, American Golden Russet, Baldwin, Black Detroit, Cayuga Red Streak or 20 oz. Apple, Colvert, Canada Red, Duchess of Oldenburgh, Early Joe, Early Harvest, Esopus Spitzenburg, Early Strawberry, Fall Janetting, Fall Pippin, Fameuse, Gravenstein, Hawthornden, Hubbardston Nonsuch, Holland Pippin, Hawley, Keswick Codlin, Kentish Fillbasket, King of Tompkins' County, Maidens Blush, Melon, Northern Spy, Primate, Pomme Grise, Red Astrachan, Ribston Pippin, Rhode Island Greening, Roxbury Russet, Sweet Bough, St. Lawrence, Swayzie Pomme Grise, Swaar, Seek-no-further Spice Sweeting, Talman Sweet, Wagener, Yellow Bellflower.

The following eleven varieties are recommended as profitable for market in the order given below, viz:—Northern Spy, R. I. Greening, Roxbury Russet, Baldwin, Fameuse or Snow apple, St. Lawrence, American Golden Russet, Red Astrachan, Early Harvest, King of Tompkins' County and Gravenstein

The following sorts are selected as being the most hardy within this division. They are recommended in the order in which they are named:—Red Astrachan, Duchess of Oldenburgh, St. Lawrence, Kentish Fill basket, Fameuse, American Golden Russet, Pomme Grise, King of Tompkins' County, Northern Spy and Gravenstein.

Mr. Beatty says the Newton Pippin and Yellow Bellflower have been tried and found too tender, but all the others say "none."

The borer, tent caterpillar and codlin moth are mentioned, but do no not seem to have been productive of much injury, except in neglected orchards. Mr. Leslie says, "by having all the fallen fruit picked up two or three times each week and fed to pigs, we have kept this enemy, the codlin moth, so much under as to make the damage done by it very trifling. Some orchards in this neighbourhood have suffered considerably from negligence in this respect." No disease of the tree is mentioned.

Spring is almost unanimously recommended as the best season for transplanting. Mr Leslie says, "fall and spring are found equally suitable. Transplanted in the fall they must have a good mulching of long manure. When manure is not convenient, bank up about the tree to the depth of about fifteen inches, which must be removed to the ordinary level soon after the frost is out. This also forms a very good protection against the barking of the trees by mice." Mr James Heslop says, "trees taken up soon after the fall of the leaf and well heeled in, have made a better growth the next season than when planted late in the spring. The reason is that the wounded root commences to heal over during the winter, and the root is ready to throw out its new fibres immediately on being planted."

With regard to dwarf trees, it seems that dwarf apples, pear and cherry have all been planted within this section, and that with suitable kinds and proper care they succeed well. Mr. Leslie says, all varieties of apple succeed as well dwarfed on the Paradise or Doucain stocks, as when worked on ordinary seedling stocks, and that the effect of dwarfing apples is to produce fruit earlier than from standards, and to make varieties that are tender or partially tender, much more hardy.

For dwarfing cherry trees the mahaleb stock is used. This he considers the best stock upon which to work the cherry, and the dwarf or low-headed form of tree the best for this climate. All varieties of cherry will succeed as well when worked upon the mahaleb as when grown as standards upon the mazzard stocks.

The pear is dwarfed by working it upon the quince stock. The roots of a quince being rather tender, he recommends to give them a heavy mulching in the fall with long manure or to bank the trees with earth, which should be removed in spring. They should have the benefit of *good shelter*, which remark applies to every kind of fruit tree grown in Canada. Clay loam is the most suitable soil for the dwarf pear. Some varieties of pear do not thrive well on the quince, and Mr. Leslie recommends the following varieties, viz:—Bartlett, Ananas d'Eté, Louise Bonne de Jersey, Duchess d'Angouleme, Flemish, Beauty, Belle Lucrative, Beurre Gifford, Beurre Diel, Sheldon, Vicar of Winkfield, and White Doyenne; and adds that much finer specimens of fruit can be produced on dwarf pear trees than upon standards.

The following varieties of pear are named as desirable sorts to plant in this division:—Ananas d'Eté, Buffam, Bartlett, Belle Lucrative, Beurre Bosc, Beurre Diel, Beurre Clairgeau, Beurre Giffard, Beurre d'Anjou, Beurre d'Aremberg, Beurre Superfin, Duchess d'Angouleme, Doyenne du Comice, Doyenne d'Eté, Dearborn's Seedling, Doyenne d'Alencon, Doyenne Gray, Doyenne Boussock, Flemish Beauty, Glout Morceau, Howell, Jargonell, Jaminette, Lawrence, Louise Bonne de Jersay, Maria Louise, Osband's Summer, Rostiezer, Swan's Orange, Seckel, Sheldon, Steven's Genneasee, Tyson, Vicar of Winkfield, Winter Nelis and White Doyenne

No varieties of pear are given as being too tender. Mr. Heslop says that the Duchess d'Angouleme has not proved as hardy as could be desired, and there is some reported tenderness of the Columbia and Bartlett, and yet that in some situations they *all* prove hardy enough for profit.

The following varieties are recommended as most profitable for market in the order in which they are given:—Flemish Beauty, Bartlett, Louise Bonne de Jersey, White Doyenne, Vicar of Winkfield, Buffam, Belle Lucrative, Sheldon, Winter Nelis, Beurre Clairgeau, Doyenne d'Eté, Beurre d'Anjou and Brandywine.

Those named as most hardy are Flemish Beauty, Glout Morceau, Vicar of Winkfield, Howell, Belle Lucrative, Sheldon, Winter Nelis, White Doynne, Tyson, Duchess d'Angouleme, Jaminette, Beurre Giffard, Easter Beurre, and Louise Bonne de Jersey.

There does not seem to be any suffering from disease or insects among the pear trees worthy of note. The pear blight is mentioned as a thing that has, as it were, been barely seen, and so of the slug and the rust on the leaf.

The following varieties of plum are named as succeeding well:—Lombard, Yellow Egg, Washington, Bradshaw, Duane's Purple, Peach Plum, Prince's Yellow Gage, Jefferson, Huling's Superb, Blue Plum, Smith's Orleans, Imperial Gage, Imperial Ottoman, Coe's Golden Drop, Green Gage, Guthrie's Apricot, and Columbia; none are too tender.

The following are recommended for profit, viz.:—Lombard, Prince's Yellow Gage, Yellow Egg, Washington, Huling's Superb, Bradshaw, Coe's Golden Drop, and Columbia. The curculio stings the fruit and causes it to fall prematurely. The only disease of the tree is the black knot. Mr. Leslie says, that all the blue and purple varieties become affected by the black knot when they attain a bearing age. The yellow varieties are much less subject to it, but cannot be said to be wholly exempt, with the exception of Prince's Yellow Gage, upon which he has not seen one of these excrescences. No insects attack the tree.

The varieties of cherry that succeed best are the common red or Kentish, Black Tartarian, Elton, Mayduke, Napoleon Bigarreau, Reine Hortense, Black Eagle, Rockport, Bigarreau, Elkhorn, Governor Wood, Late Duke, Yellow Spanish, and Plumstone Morello.

No variety of cherry is named as being too tender, but Mr. Leslie advises that all cherry trees be planted in sheltered situations where trees, buildings or the like will afford them some protection.

The Black Tartarian, Kentish, Mayduke, Black Eagle, Elton, Napoleon Bigarreau, and Rockport Bigarreau are said to be the most profitable for market.

No disease affecting the tree; Mr. Leslie mentions bursting of the bark occasionally by extreme cold weather, which he says can be wholly prevented by growing them with low heads. The insects are the slug on the leaf and the curculio in the fruit.

In the eastern part of this division the peach cannot be grown; in the westerly extremity near Hamilton, Dundas and Ancaster, it can be grown in the open air in dry warm soils and in sheltered localities, yet even here the fruit is now very uncertain, much more so than in former years.

The climate throughout this division is not favourable to the growth of the quince, apricot or nectarine. Like the peach, they can be made to fruit in favourable and sheltered situations or when trained on a wall.

Strawberries will do well. The favourite kind is the Wilson; besides which the Triomphe de Gand, Jucunda, Trollope's Victoria, Agriculturist, Nicanor, Russell's Prolific, Downer's Prolific, Hovey, &c., are named.

All name Wilson as the best for market; two add Triomphe de Gand; and Mr. Leslie adds to these Jucunda, and, for a near market, Downer's Prolific.

The following varieties of raspberries are found to succeed here, viz:—Franconia, Brinkle's Orange, Red Antwerp, Fastolff, Hornet, Philadelphia, Clarke, Black Cap, Prince of Wales and Fillbasket.

The following sorts are recommended to be planted for market in the following order:—Brinkle's Orange, Franconia, Clarke, Black Cap and Fastolff. Mr. Leslie says he has not seen any better market variety than the Franconia, which proves with him to be vigorous, hardy and productive, and the berry firm and fine flavoured.

The following gooseberries are recommended in the order below:—Houghton, Whitesmith, Crownbob, Warrington Red, Hearts of Oak, Red Ironmonger, and a seedling raised by John Brooking of Dundas, which is very like the Warrington, but has not yet been tested on light or sandy soils.

The English varieties of gooseberries are subject to mildew, especially on light soils. Houghton's seedling, and the before mentioned Brooking's seedling, as far as tried, are not subject to mildew. Mr. Leslie says the Houghton is a very useful and profitable berry, and should be largely grown for market.

Flour of Sulphur is found useful in preventing or mitigating the mildew. Lime, ashes and salt, with a coarse mulch, are also used. High cultivation, thorough pruning, and a strong soil are essential aids.

But few blackberries seem to have been grown. Mr. Leslie says, "the Lawton or New Rochelle is too tender, being killed nearly to the ground every winter; the Wilson, a little hardier, producing a small quantity of good fruit each year; but does much better when protected with a covering during winter. The Kittatinny is the best of all—is the hardiest, killing back but a few inches—and produces good crops of excellent fruit.

All varieties of currants thrive well. The White Grape, Cherry and Black Naples, are the most popular. There is no disease of the plants. The currant borer does some slight injury by boring through the pith of the stems; and the sawfly worm has done considerable damage by eating off the leaves. Mr. Leslie says these (the sawflies) are rapidly disappearing where pains are taken to kill them with white hellebore.

Some thirty varieties of grapes are mentioned as having been planted; of these only the Rebecca have been found to be too tender. The Clinton, Delaware, Concord, Hartford Prolific and Adirondac, are reported to be perfectly hardy; but Mr. Cooley says that *all* require protection during the winter. Those that ripen their fruit every year are the Clinton, Delaware, Concord, Hartford Prolific, Adirondac and Allen's Hydrid.

Mr. Leslie mentions a small vineyard of two acres, planted with Clinton, Delaware, and Hartford Prolific; and some foreign vines.

Mr. Burnet says there are some thirty-five acres of vineyards around Hamilton, planted with Delaware, Clinton, Concord, Salem, Iona and Oporto.

There is also a vineyard at Cooksville, probably the largest vineyard in the Province, planted mainly with the Clinton, in which the fruit attains a high degree of perfection.

No diseases of the vine are mentioned, and the insect depredations as yet have not been material.

The soil is of every character, from light sand to heavy clay, but clay loam predominates. In some parts the subsoil is gravelly, or a shale. The best apples and pears are those grown upon a clay loam with a somewhat porous subsoil. The best grapes are raised on loamy soil with a gravelly or a shale subsoil. Land that is rolling is preferable to that which is flat or low. Gooseberries and plums succeed best on heavy clays, pears on clay loam, apples on clay and sandy loam, cherry and peach on lighter sandy and gravelly soils. The extremes of temperature are ordinarily from fourteen degrees below zero to 95 degrees above, in the shade, though at times it has fallen considerably lower.

Mr. Leslie calls attention to a seedling strawberry on the grounds of Mr. John Cross, Oakville, named by him "Long John" from its peculiar shape. He says "it is a large berry and of good quality. The plant is much more robust and hardy than the Wilson, while its productiveness is fully *one-third more*, thus placing it at the head of the list for market berries. It has been planted and tested side by side with the Wilson for some years, and has fully borne out these statements. To the enormous productiveness I can bear testimony, having been an astonished witness thereof."

Mr. Leslie also adds that the Transcendant, Golden Beauty, Montreal Beauty crab apples are the favourites in this locality. A seedling crab with a distinct quite sweet flavour, raised by George Leslie & Son, promises well, the tree being, like all other crabs, very hardy, while the fruit cooks as well as the sour varieties, and requires only a modicum of the sugar.

Storing Winter Apples.

A correspondent of "Laws of Life," who claims to have had extended experience, is decidedly of the opinion that apples keep far better when put into close boxes or barrels, and secluded as much as possible from the air. When thus stored, he says they will come out in spring full and plump as when taken from the tree. Many varieties, as the Talman Sweet, Spitzenburg, and those kinds that are not considered as long keepers and shrivel badly, will do well treated in this way. I have, he continues, found universally, that they keep better to let them lie without picking over. It is much better to pile them into a large bin across the cellar, say six or seven feet high and four or five feet wide, and cover them up tightly, than to lay them on shelves.

I once saw such a bin that a man had kept through the winter. About the first of April he thought he would open the windows on the side of the cellar next the window to let in the air, that they might keep better. I was at his place and he my called attention to the fact. Two windows just over the bin were opened about ten days or two weeks, and the apples exactly opposite the windows about one-third rotted for as much as a foot in depth, and the remaining part on either side were not rotted at all.

Another instance: A neighbour of mine had about five hundred bushels in a pile in a cellar. As they became a little specked he commenced picking them over; when about half done, he got tired and concluded to let them go. When marketed about six weeks after, he found that about one-third of those picked over were not fit for market, while all but about one-twentieth of the others were good. This I have seen in numerous instances. If you wish to try the experiment, make a box as tight as a carpenter can make, and when picking from the orchard fill it and nail it fast. Let it lie in the orchard till it is in danger of freezing; then put it in the cellar. Put the same quantity on shelves for trial. I am pretty sure one experiment will convince.

NOTE BY THE HORTICULTURAL EDITOR.—The most convenient and, at the same time, the best way of handling apples for winter use is to select a cool, dry day, gather the apples carefully by hand into baskets holding about one peck, being careful to put into them only perfectly sound apples. Take dry barrels into the orchard, and place the first basketful into the barrel by hand, afterwards the basket filled with apples may be put into the barrel and the fruit carefully poured out. This should be done slowly and gently, allowing the apples merely to *roll out*, not *fall* down on to the fruit already in. As each basket is emptied into the barrel give the barrel a shake sufficient to settle the apples snugly and compactly into their places. Fill the barrel in this way even with the top of the staves, leveling with the hand by placing the apples so that there will be as little unoccupied space as possible, then put on the head, pressing it down to its place with the hand screw packer; drive on the hoops tight and nail a small strip to hold the head in place. The barrels, when filled and secured by nailing, should be taken out of the sun, and placed in a shed, open to the north, and remain there until there is danger of the apples freezing, when they should be removed to the cellar, which should be kept cold, barely free from frost, and the barrels opened as the fruit is wanted for use. If no such shed is at hand, let the fruit be stored in the cellar at once.

The American Sweet Chestnut.

We desire to call attention to this very valuable tree, and suggest to our farmers that they should plant it, especially those who have any light soil on their farms, though it thrives exceedingly well on clayey, loamy, gravelly, and rocky soils, indeed anywhere that the ground is not cold and wet.

The farmer should plant this tree because it is a hardy, native tree, thriving well from the shores of Lake Huron to Lake Erie; because it grows rapidly, bears fruit in a very few years—about as soon as most apple trees—which sells at from three to four dollars per bushel; and because the timber is very valuable even now, and is fast becoming more so; and if not available to the planter himself, will be of great value to his children.

Small nursery-grown trees can now be had of our leading nurserymen, which can be transplanted with entire success, and at a cost not exceeding that of apple trees.

The landscape gardener will not fail to use this tree abundantly wherever suitable, for it ranks with the oak, the king of the forest, in landscape gardening. It attains an enormous size, and is almost as remarkable for its longevity. The celebrated chestnut tree at Tortworth, in the county of Gloucester, England, measures nineteen yards in circumference, and is believed to have been standing before the Conquest, 1066.

Downing says of the chestnut that "when old, its huge trunk, wide-spread branches, lofty head and irregular outline, all contribute to render it a picturesque tree of the very first class. In that state, when standing alone with free room to develop itself on every side, like the oak, it gives a character of dignity, majesty and grandeur to the scene, beyond the power of most trees to confer. It is well known that the favourite tree of Salvator Rosa, and one which was most frequently introduced with a singularly happy effect into his wild and picturesque compositions, was the chestnut; sometimes a massy and bold group of its verdure, but oftener an old and storm-rifted giant, half leafless, or a barren trunk coated with a rich verdure of mosses and lichens.

"The chestnut in maturity, like the oak, has a great variety of outlines; and no trees are better fitted than these for the formation of grand groups, heavy masses, or wide outlines of foliage. A higher kind of beauty, with more dignity and variety, can be formed of these two genera of trees when disposed in grand masses, than with any other forest trees of temperate climates; perhaps we may say of any climate."

It is but a very few years since Mr. Robt. N. Ball, of Niagara, planted a few chestnuts, and from these raised some little trees which he transplanted on the lawn, that now not only are an ornament to the grounds, but yield a profusion of nuts. From this it may be seen that the tree is one of rapid growth, and that the planter may reasonably expect to enjoy much of the fruits of his labour in planting the chestnut.

On Melons.

The cultivation of melons has always been a specialty with me, and many are the failures I have made in their production, but during the past two seasons I have hit off what I consider to be the correct plan of growing this really delicious fruit in profusion and perfection for my own table. My plan is as follows:—

About the first of April, having a hotbed in good order, I start the plants in sods turned upside-down, and when the first two leaves after the seed leaves have formed, plant out in a cold frame; this may be done about the middle of the month.

Although the preparation of a cold frame is a very simple affair, yet, as some of your readers may not have had any experience in their construction, I will give them my method:—

Drive four stakes firmly into the ground at a proper distance apart, so that when boards are nailed to them, the end frames of the sashes provided will rest on the boards nailed to these stakes. I use my double windows, which are six feet long, and having nailed twelve feet boards to the stakes, three sashes side by side nearly extend the whole length. The sashes must have a fall of about eight inches to the south, two boards being used for the back, and one for the front. The proper slope can be obtained by sinking the back boards or raising the front as desired before nailing on. The main thing is to have these boards level, so as not to wring the sashes. After getting the sides properly adjusted, cut boards, so as to fill up one end; lay on the sashes, and fill up the other end with boards in the same manner, driving in the stakes to hold the end boards in their places. Then bank up with earth all round to make the frame tight.

The next thing is to enrich the earth in which the melons are to be grown. To do this, dig out two round holes, two and a half feet across, towards each end of the frame, two spades deep, and fill up with equal parts of sandy loam or rotted sods, and well decomposed manure thoroughly mixed. Put three plants into each *hill*, which should be slightly *depressed*, being at least two inches in the centre below the rest of the soil; this serves to hold the water when applied by the watering-pot. Having set out the plants, as before directed, about the middle of April, keep them moderately cool by giving air, that is, shifting the sashes, if the days are very bright, so as to allow air to pass between them, and watering daily until thoroughly established. (If the plants are grown in a good thick sod they ought not to wilt at all; wilting checks the growth, and should by no means be allowed.) In three or four days the sashes may be kept pretty close; always shut on cloudy days and at night, and in bright weather keep up a heat of from eighty to ninety degrees, watering the plants freely every other evening, and when they begin to run pinch off the main vine, so as to make the plant branch out.

It will be noticed that there are no female flowers on the main vine, and consequently no fruit. The fruit-bearing branches are what are in grape culture called the laterals. In June they will begin to flower, and at the end of that month the runners will fill up the frames. The weather at this season will be at its hottest, and the sashes may be removed, the boards knocked down, and the earth levelled, so as to give free scope to the melons to run. The first week in August, the vines may be stopped by pinching off the ends, as no fruit will set and ripen after that date. Ripe melons may be expected on or before the first of August, and a good supply will be gathered every day for two months.

When the fruit begins to ripen no more water should be applied, and, in fact, unless the weather is quite dry, very little water after the sashes are removed. It will be found that the vines will have done bearing before cold nights and days come round, at which time the melon tastes, in my opinion, more like a very bad turnip than anything else, perfectly devoid of sweetness and flavour.

Results—From two of these frames the youngsters kept count of the fruit gathered, and the produce was ninety-three, chiefly nutmegs and canteloups, of the sweetest and most exquisite quality.

The method practised by some of growing melons in hotbeds is decidedly erroneous.

My experience goes to show that they are entirely lacking in flavour. It will be found highly advantageous, when putting out the young melon plants into the cold frames, to plant out in rows, also from the hotbed, the young tomato plants and some lettuce for early use. The tomatoes will make much stronger, stockier plants in the cold frame than they will with bottom heat, which tends to make them thin and sickly. From tomatoes grown in this way fruit may be gathered about the 20th of July. Of course, when they touch the glass in the cold frame they should be set out in the open ground.

Ottawa. P. E. BUCKE.

The Twenty-four First-prize Roses

At the great Crystal Palace Rose Show, held last June, where the competition is probably the keenest and the standard of excellence the highest of any place in the world, the collection that received the first prize contained the following names :—

COMTESSE DE CHABRILLANT, a lovely pink colour, very perfect, and beautifully cupped.

MARIE RADY, not known to us, probably has never been bloomed in this Province.

MAURICE BERNARDIN, a rich vermilllon rose, of large size, and very fine form.

MARECHAL NIEL, a most beautiful deep yellow tea-scented flower, of large size and and very sweet.

HORACE VERNET, very large, a beautiful velvety purplish red, shaded with dark crimson.

JOHN HOPPER, also large, clear rose colour, with crimson centre.

XAVIER OLIBO is velvety black, shaded with amaranth, large and full.

MARQUERITE DE ST. AMAND is a most abundant bloomer, flowers large, full, of fine form, and a rosy flesh colour.

PRINCESS MARY OF CAMBRIDGE, of a pale rose colour, quite full, and of good form.

LE RHONE, a rich and brilliant vermillion, flowers large and full,

DUKE OF WELLINGTON is a bright velvety red, shaded with blackish maroon, with a fiery red centre.

EDWARD MORREN, also unknown to us.

MADAME NOMAN is pure white, of medium size, but fine form.

MARIE BAUMAN; this is very large, smooth and nicely formed, of a bright carmine colour.

DEVONIENSIS, a tea-scented rose, very large and full, of a light yellow colour, very fine for pot culture.

SENATEUR VAISSE is large, very double, and of a beautiful bright red.

MADAME VIOLET; the flowers are large and full, in colour transparent flesh, shaded with rose.

MADAME CLEMENCE JOIGNEAUX, very large size, the colour red, shaded with lilac.

VICTOR VERDIER is a very showy flower of a rosy carmine, with purplish edges.

MADAME CHARLES WOOD, a very large and effective flower, of a clear vinous crimson colour.

ANTOINE DUCHER is a very fine flower, very large and full, in colour bright red.

ALFRED COLOMB is bright fiery red, of a fine globular form, and very effective.

DR. ANDRY, one of the most showy, being very large and full, of fine form, and dark bright red colour.

MADAME LA BARONNE DE ROTHSCHILD, a most beautiful flower, colour clear pale rose, shaded with white, very large and double.

Those of our readers who wish to confine their collection to a dozen of the choicest roses, may order of their nurseryman the following names, with every assurance that they will do well in our climate, and satisfy every reasonable expectation. They are among the very best, and we esteem them as perhaps the very best dozen roses it has been our privilege to plant. We name them Alfred Colomb, Antoine Ducher, Boule de Neige, Comtesse de Chabrillant, Duke of Edinburgh, Madame Alfred de Rougemont, Madame la Baronne de Rothschild, Madam Charles Wood, Maurice Bernardin, Prince Camille de Rohand, Victor Verdier, and Xavier Olibo.

Those who wish a few choice roses for window culture will be well pleased with Devoniensis, Madame Alfred de Rougemont, Maurice Bernardin, Modele de Perfection, Souvenir d'Elise Vardon and Souvenir d'un Ami.

How to Make a Lawn.

The ground should be entirely free from stagnant water. It must be trenched or trench-ploughed to the depth of eighteen or twenty-four inches. A week of hot, dry weather will be sufficient to dry up the grass on a thin soil, whilst on a deep, well-prepared soil, a whole month of drought would fail to destroy the verdure. The depth, whatever it may be, should be uniform, for if it be deeper in some places than in others, the deep places will settle and make the ground uneven. Evenness of surface is of great importance. I do not mean level, for an undulating surface is quite as desirable for a lawn as a level one, but whether level or undulating it must be smooth and free from even the smallest stones, as these interfere with the operations of the mowing machine.

Red-top is the best grass for a lawn, about fifty or sixty pounds to the acre. Fifty pounds will be sufficient if the seed be clean and good, which it seldom is. Some people recommend white clover, say one-fourth, to be mixed with the red-top, and this does very well, but I prefer the pure red-top. Early in the spring is the best time for seeding a lawn. All preparatory work should be performed in the fall, so that during winter the ground may settle, and any defects that may be developed can be corrected before sowing. In spring, at the fitting moment, give a light ploughing, a good harrowing, pick off the stones, sow the seed, and give it a good rolling, which finishes the work.

By sowing early in the spring you may have a respectable lawn before midsummer. —*P. Barry's address before the Geneva, N. Y., Agricultural Society.*

Hickory Nuts.

Cracking hickory nuts is one of the pastimes of boyhood that men seldom forget. But with all its popularity, and the almost universal acknowledgment of the good qualities of the hickory nut, very little has yet been done to improve or propagate the best varieties. The common shell bark (*Carya alba*) and the pecan nut (*C. olivæformis*) are generally admitted to produce the best nuts; but there is a great difference in the size and quality of these, and varieties are abundant, some of which are far superior to others.

To produce improved varieties from seed would be a slow and tedious process; but it can, and will be done, although at present we may well be satisfied with the very best natural seedlings that can be found in various sections of the country. The hickory is a difficult tree to propagate by the ordinary methods of budding and grafting; and we should be happy to hear from any of our readers who have been successful in propagating it by either of these methods. At present we do not know of any better plan than to splice or cleft graft the young seedlings.

Believing that there are varieties of hickory nuts worthy of propagation as well as for the purpose of receiving distinct names, we shall endeavour from time to time to call attention to some of the very best, and we commence the list with

HALE'S PAPER SHELL,

a most superior variety of the shell bark hickory, which originated near Ridgewood, N. J. The nuts are large, varying from an inch to an inch and a quarter long and about the same in width. Shell thin, and instead of the regular corrugations running from base to point as usual in varieties of this species, the entire surface appears to be broken up into small depressions, which gives it a wavy appearance somewhat similar to the English walnut. The Hale's is certainly one of the most distinct and valuable sorts that we have ever seen. There is one seedling of the Hale's standing near the original tree, which is now thirty years old; but the nuts are quite distinct from those borne by the parent tree; and this fact shows that the only certain way of perpetuating distinct varieties of hickory nuts will be in the usual mode adopted with fruit trees.—*Rural New Yorker.*

The Beurre d'Anjou Pear.

This is one of the most valuable pears in cultivation, and deserves to be most widely disseminated. The fruit is of large size and fine appearance, the skin of which is yellowish green, sprinkled with russet, and often presenting a dull crimson cheek on the sunny side. The flesh is melting and juicy, very nicely perfumed, and having a brisk vinous flavour, ranking in quality among the best. It is usually ripe in November, but will often keep until January. The tree is vigorous and very productive, and seems to be likely to prove hardy, so as to thrive well where pears can be grown.

The fruit is much sought after in the city markets, and last year sold readily in the Boston markets at $30 per barrel.

THE FARMER'S CHRISTMAS FLOWERS.—Besides the Everlastings, which can be cut in summer and laid away in a drawer for the decorations of the holidays, the double geraniums furnish a showy and most beautiful bouquet. If these are cut when the truss is in perfection, and carefully dried in a dark drawer, they will keep their colours perfectly and not drop a petal. Tastefully arranged with a few sprigs of evergreens, they make a most showy ornament for the Christmas dinner table.

Protection against Mice.

To the Editor.

SIR,—Mr. W. H. Mills' plan of protecting fruit trees from mice during the winter may be very good in some places, particularly where tiles may be easily procured and where the snow is not very deep, but tiles would not be of much use in many parts, especially where the snow falls to a depth of two to two and a half feet. I saw plenty of apple trees last spring that had been peeled to a height of five feet, even up into the limbs. It was the outside row of trees nearest the fences, where the snow had been drifted, for the mice will work as high as the snow lies. To make sure work with tiles, they would require to be at the least two tiles deep. In this township last winter there were hundreds of trees killed by the mice—some that had been planted for six years and were bearing well. One man estimated his loss at not less than a hundred dollars.

I have about three hundred trees, none older than seven years planted, and I did not lose one tree by mice, nor even have one bitten by them, although there are some fifty pine stumps in my orchard, which are good harbours for mice. Indeed, the ground last spring was riddled by them, but no trees were touched.

My plan of protecting the trees is simple, and within the reach of all, not costing over one-twentieth of the price of Mr. Mills' tiles I use white lead and linseed oil, putting in a little lamp-black to colour nearly of the colour of the bark. I make a good thick paint and put on with a brush. It is

Protecting Strawberry Plants.

In those parts of the Province where snow cannot be relied upon to cover the strawberry plants all winter, some protection should be given them to insure a full crop of fruit. When the plants are not covered through the winter by the snow, they are subjected to so many freezings and thawings that the fruit buds, already formed and lying concealed within the crown of the plant, are injured. A very slight covering is all that is required—a few evergreen boughs or leaves, or thin covering of straw. A thick covering is apt to keep the plants too warm, which proves to be equally as injurious as too much exposure. Every one can have an abundance of strawberries any year, at the cost of a very little care and labour The Wilson has proved to be the most productive and hardy everywhere of any variety in cultivation, and when fully ripe is a much higher flavoured berry than the Triomphe de Gand, which is usually grown as the next most profitable sort.

The Weeping Mountain Ash.

This is a variety of the common mountain ash, which has a drooping habit, and on that account makes a very pleasing object on the lawn. It is propagated by grafting the drooping variety upon the common mountain ash, at such a height from the ground as it is desired to form the head, for it droops so much that it increases but very little in height above the place where the graft is inserted. It bears berries like the common kind, as shown in our engraving, which gives our readers a very good representation of the general appearance of the tree It is very hardy, and will thrive in any part of the country, so that no one need hesitate to plant it. It is particularly appropriate for cemeteries, where it may be very advantageously planted with other drooping trees.

good for the trees into the bargain. White lead is a poison, and mice have four good, strong senses, namely, sight, hearing, taste, and smell. It will also prevent the apple-tree borer in summer, and it is good for wounds of all kinds on trees, whether by pruning or from accidents.

A large number of apple-trees were lost last winter by bark-splitting at the bottom. The cause I believe to be this—when it rains in winter the water runs down the trees to the ground, lodges in a small pool and freezes round the tree. Bank the trees with earth, a few inches higher than the ground around, so that the water will run away instead of lodging, and no fear of bark-splitting. In general there is a hole or depression around the stems of trees at the root; before the winter sets in, fill this up, and avoid the loss of valuable trees in spring.

AN OBSERVER.

Craigvale, Nov., 1870.

Such practical suggestions are always valuable, and always welcome—ED.

The winter meeting of the Fruit Growers' Association of Ontario will be held in the Court House, in the City of Hamilton, on Tuesday, the seventh of February, 1871, commencing at 10 o'clock, a.m., and continuing through the evening.

CHESTER SEEDLING GRAPES.—F. R. Elliott writes to the *Rural New Yorker* his doubts concerning the value of these seedlings in the climates and soils, the rough care and culture, of the majority of our grape growing sections.

SUMMER PINCHING OF RASPBERRY AND BLACKBERRY CANES.—A correspondent of the *Gardeners' Monthly*, writing from Illinois, says that he has found much benefit by pinching back the canes of raspberry and blackberry plants in July, and enumerates them thus: 1st. Increases the size and self-supporting capacity of the main canes. 2nd. Increases the number of side branches, and consequently the quantity of fruit.

USEFUL MANURE FOR RASPBERRY PLANTS.—Mix equal parts of sawdust and stable manure, and place the compound around the roots every fall before the snow comes. This mixture tends not only to keep the roots warm during winter, but the sawdust, by partially decomposing, furnishes a quantity of potash which is very requisite food for the growing plants. Grape vines may be treated in a similar manner.

THE WEEPING HEMLOCK.—There is an illustration in the *Rural New Yorker* of a new weeping variety of the hemlock, which must make a very handsome addition to our collection of hardy native evergreens. It seems to have been discovered by H. W. Sargent, Esq., of Fishkill, N.Y., growing among some young seedling hemlocks. Grafted some feet from the ground on stocks of the common hemlock, it forms a very pretty drooping head of light feathery evergreen spray.

Poetry.

SEA VENTURES.

I stood and watched my ships go out
Each, one by one, unmooring free,
What time the quiet harbour filled,
With flood tide from the sea.

The first that sailed, her name was Joy,
She spread a smooth, white, shining sail,
And eastward drove with bending spars
Before the sighing gale.

Another sailed, her name was Hope,
No cargo in her hold she bore;
Thinking to find in western lands
Of merchandise a store.

The next that sailed, her name was Love,
She showed a red flag at her mast.
A flag as red as blood she showed,
And she sped south right fast.

The last that sailed, her name was Faith
Slowly she took her passage forth,
Tacked and lay too; at last she steered
A straight course for the north.

My gallant ships they sailed away,
Over the shimmering summer sea;
I stood at watch for many a day—
But one came back to me.

For Joy was caught by Pirate Pain;
Hope ran upon a hidden reef,
And Love took fire and foundered fast,
In whelming seas of grief.

Faith came at last, storm-beat and torn,
She recompensed me all my loss;
For, as a cargo safe she brought,
A Crown linked to a Cross.

—*Boston Cultivator.*

The Winter Snows.

Over the mountains the snow-wreaths are drifting,
Hanging their garlands on laurel and pine,
Robing the fields with an exquisite beauty,
Bending the feathery sprays of the vine,
Falling like down on the breast of the river,
Crowning the maple trees over the way,
Drifting along on the winds to the southward,
Hiding the vessels far out in the bay

In the red sunset the snow-flakes are shining,
Snow-drift on snow-drift, and curl upon curl,
Flashing back colours of exquisite brightness,
Diamonds and rose-leaves and mother-of-pearl.
Softly, ye snow-wreaths, drop over the hill-side
Where in still slumber the weary ones rest,
Where by the pine-tree my mother is sleeping,
Tenderly lay your white folds on her breast.

Soon shall the spring-time break over the mountains,
Over its beauty no cold wind shall blow;
Frost shall not breathe there to wither the flowers,
Never again shall they hide in the snow;
Eye hath not looked on that spring in its beauty;
Songs of the seraphs shall welcome its birth;
Come in the beauty and glow of the morning,
Spring-time eternal, dawn over the earth!

Architecture.

Building Houses without an Architect.

I had an excellent kind friend, and also an old worthy female servant. They each wanted a house, and, as I had some experience in almost all kinds of Canadian work, and also wished very much to make some return to both my friend and the old servant, I offered to buy them each a lot and build two houses. There was a vast difference in the kind of house required; my friend's was to be a handsome imposing brick edifice, to cost some $2400, and his lot was set down at somewhat over a thousand dollars outlay; whereas the old servant's lot must not exceed $400 in cost, and the house must be built for her at a cost of $100, and not to exceed this amount—indeed she had no more money.

This work, the first of the kind I ever attempted, is now complete; and I may say, what few young architects can, it is complete without a mistake of any kind. I may except one, which is more an alteration than a mistake, but it needs no particular description, and only amounted to enlarging one room at the expense of another, thereby equalizing them both.

Now I may safely state than an architect is *not always necessary*, and in our case we should have had to pay him over one hundred and forty dollars for just doing what I myself did. And the only safe thing for any of my readers—who are going to build, and who are also going to dispense with an architect—to do is, just to carefully draw the ground plan of the house, show everything, doors, windows, partition, chimneys, and all, do not leave one iota to be contrived or introduced, or "seen about," when the lower floor is built. Do the same with all other flats, draw them all most carefully; and also draw each joist and trimmer in it. When you have done this with every floor from the ceiling to the garret, staircase and all, begin on the outside, and draw four or more views, one for each side, and put in every window and door, water spout and descending pipe, so that you can see at a glance what every view will embrace and require. Do this with roof and also each view of it. Next we come to particulars—windows and doors. Proceed to draw a window, the very same you design to have, but do this last plan on a very large scale, say one inch to the foot at least, and draw every view of the window—sides, sill, top and sash, each in its turn, but so drawn, even to the moulding, as will show every view of your window; and this one window will answer for all others. Do the same with a door, and this one, outside or inside door, will also answer for all else. If you want any plainer door, draw it also; draw everything, and you will find that although when you begin you will know nothing about drawing plans, when you have given five or six evenings to the various details here discribed you will wonder *how much you have learned*, and in how short a time. And this is the true way to knowledge; the way, simple as it seems, that all great and self-made men have been formed. In fact, the only way, for if you wait for instruction on every point and your mind is too indolent to think it out for yourself, for the most part you will never do to build a house without an architect; you may quite rely on that. Nor, indeed, is it probable you will ever do anything but work for some one whose mind is not too indolent, or whose body too lazy to carry out any project he may determine on as feasible and within his reach.

Suffice it further to say, that both the houses were completed, and also almost to time, and neither cost more than was estimated, except where some extras were introduced, which were well afforded and did not cost much. In some future article I will give a description of the buildings and the cost. One thing I am quite sure of—no small family need pay rent who have $100 wherewith to build a small house of three rooms of 12 by 9, 12 by 12, and 12 by 9.

These three measurements were the size of the $100 edifice, and when I first married I lived in one much worse for some years, until I determined to build one for myself, and did so at a cost of $125. Some description of this house, which was built of clay unburnt bricks, may at a future time interest some of the readers of the FARMER.

The present $100 dwelling was, however, built of frame, and plastered inside. C.

Foundation of Houses on Sand.

It is not generally known that foundations for large and heavy brick buildings can be quite safely constructed on quicksand, even where your foot will sink rapidly when pressed on it, and also where the sand is full of water—the only requirement to ensure a perfect foundation under these conditions being that no future operation will allow of the escape of the quicksand, and that the base or lower bearing of the building on which the walls are to be erected should be first constructed of two-inch plank laid crosswise, say about three or four feet in width. On this should be laid another layer of two-inch plank, but this should be laid lengthwise, crossing the lower tier. For very heavy walls another crosswise layer of planks may be laid; but for all ordinary heavy buildings, such as mill walls, the above two ply of two-inch plank will be found sufficient. The fact of water being on the sand will not hurt the stability, or injure the walls in any way; nor will any settlement be as likely to take place as on ordinary soft clay, strange as it may seem. But beware of under-draining *after* the building is constructed, and thus removing the water from the sand. There will in this case be imminent danger of settlement; the quicksand, deprived of its water, will at once allow of alteration in relative levels. C.

Household.

Farmers' Daughters.

There can be no question that the mutual influence of the sexes in families is fraught with advantage to all parties concerned. It is a matter of common observation and experience that boys or young men who have been brought up without sisters, are more rough, uncouth and boorish, than those whose manners and tempers have been softened by female intercourse at home. It is equally true that the presence of brothers in a household is of no small importance in moulding the character of sisters. This is most marked when the brothers, or at least one or two of them, are the older. The girls in this case will always exercise, both towards each other and their brothers, more forbearance and sweetness of temper than where there is not this intermixture of sexes. Boys and girls, however amiable, will be more quarrelsome with these of their own sex than when under the harmonizing and restraining influence of the other. Of the tender and ennobling influence of the mother over the son, every man while a spark of goodness lingers in his breast will carry some trace and softening memory to his dying day. It is here, indeed, that woman's highest mission lies; and while she has the noble task of moulding men's characters, and instilling into their souls all that is purest and best in human nature, she need not descend from her lofty sphere into the dusty arena of politics. Very few *mothers* trouble themselves about the *ballot*, or care for the franchise in any form.

It is true that domestic cares, in this country especially, often press too heavily on women, and their life is sometimes one of too little varied drudgery; but nevertheless it is no doubt best for them to know something of household cares.

Our belief is that a due proportion of duties and recreation constitute the *summum bonum* of female happiness. We do not mean that girls shall have too much absolutely hard work to do, and of course altogether object to their having to engage in out of door farm labour; but we hold that they are both better and happier, as wives and mothers, when the necessary home duties have formed, before marriage, part of the daily routine of the daughter's life. To do otherwise, is simply to make any girl feel, that having married has made her life harder and her lot worse rather than better, and with these feelings rankling in her heart, she will be always more easily vexed and "put out," when any little misunderstanding takes place with her husband, than if the duties above alluded to were so familiar as to make no such painful impression on her mind.

By all means let our daughters discard the idea of there being anything to be ashamed of in household work. Sensible young men would rather see them in neat and appropriate dress "making biscuits," than know that they have rushed from some such employment, on the announcement of a visitor, to re-arrange their toilet and put on with "company" dress "company manners," from which all naturalness has fled. A loving woman with neat-handed skill in home comforts is more attractive and more helpful and happy than all the "fine ladies" in the world. Depend upon it, where two young people begin housekeeping together, even when their means are not straitened, the household will be far better managed and mutual happiness more surely attained, if the wife looks on her family duties as her pride and pleasure, than if she regards them as a burden and a tax from which she will escape as much as possible.

PASTE THAT WILL KEEP A YEAR.—Dissolve a tea-spoonful of alum in a quart of warm water. When cold, stir in flour to give it the consistency of thick cream, being particular to beat up all the lumps; stir in as much powdered rosin as will lay on a dime, and throw in half a dozen cloves, to give a pleasant odour. Have on the fire a tea cup of boiling water; pour the flour mixture into it, stirring well all the time. In a few minutes it will be the consistency of mush. Pour it into an earthen or china vessel; let it cool; lay a cover on, and put it in a cool place. When needed for use, take out a portion and soften it with warm water.

THE CHILD'S CORNER.

The following lines and the moral appended were sent to us by a little girl, eleven years old. We are always glad to encourage the little ones, and especially to foster in their minds such sentiments as are here expressed.

There's a Streamer of Crape on the Latch of the Gate.

There's a streamer of crape on the latch of the gate
When the sun shines bright and fair;
And the children say, as they play on the green,
"There's somebody dead in there."

There's a streamer of crape on the latch of the gate,
And a lady comes forth from theuce,
"My darling is gone!" she says to the throng
That is waiting about the fence.

The streamer of crape is removed from the gate,
But to be placed there again,
For the God who took the daughter away,
Called the sorrowing parents to Heaven.

MOTHERS.

Children, you will never have another mother. Be careful to obey her every word, and earnestly attend to all her wishes. If you do this, there will not be so much remorse when the loved one is taken from you. You can think in after times, when you call her to mind, that there was one comfort, and that comfort was that you never did anything to displease her.

MAUDE.

Agricultural Intelligence.

Sale of Thorough-bred Stock.

An auction sale of Short-horns, Cotswold sheep and Berkshire swine, belonging to Mr. John Miller, took place according to advertisement, on the 16th of November, at Thistle Ha', Pickering. There was a good attendance of buyers, and the sale was quite successful. The first lots offered were the Cotswold sheep. Eleven imported ewes were sold, of which one pair brought $220, another pair $200, and the rest ranged from $170 down to $94 per pair. Fourteen ewes, bred on the farm, brought from $40 to $80 the pair. Only two of the rams were put up, the season being late. These fetched $100 each. Five Berkshire boars brought from $18 to $41 each.

Of the Short-horns there were eight cows, eight heifers, and eight bull calves. The total sum realised for the twenty-four cattle was $3634, giving an average of $151 per head. The highest price obtained was for the cow Maggie 2nd, that with a heifer calf by her side brought $310. $291 was given for another cow, Camellia, and several fetched over $200. Mr. Morgan, of New York State, gave the highest price, $200, for a heifer. The bull calves also brought good prices, making an average of $120 per head for the lot. The highest price for any one calf was $180.

Trial of Double-Furrow Ploughs.

A public trial of two of these ploughs took place at Milliken's Corners, Markham township, on Monday, November 14th. The day being wet and stormy, but a small attendance of farmers was on the ground, the number of spectators not exceeding fifty. Of the ploughs brought out one was made by John Gray & Co., Uddington, Scotland, and imported by Wm. Rennie, of Eglington, York township. The other was made by R. Mitchell & Son, Peterhead, Scotland, and imported by C. Brodie, Gormley, Markham township. The ploughs set to work about 2 p.m., in a field of good strong timothy sod, the soil a rich loam interspersed with small stone. One pair of horses drew each plough. The work done by both was not only entirely satisfactory, but greatly exceeded our expectations; and was superior even to what can be accomplished by the best ploughman. The work done by the Gray plough seemed the best, the furrows being more smoothly and evenly laid, and set up at a better angle than those of the Mitchell plough. Each furrow cut was 12 inches wide by six deep. For want of a dynometer we could not ascertain the amount of draft of the respective ploughs, nor how it would bear comparison with that of the ordinary single-furrow plough; but the general impression seemed to be that with three horses such as are ordinarily used, and as a faster gait attained, it would be easy work to pleugh four acres of land in an ordinary day's time. The teams used were heavy Clydesdales, and accomplished their work with apparent ease, yet their gait we thought to be too slow, as compared with ordinary ploughing. The machines themselves are somewhat complicated, requiring no handles for guidance, the work being controlled by three wheels on which the machine runs, which go a great way towards lightening the draft. From what we saw at the trial we are satisfied that the double-furrow plough will prove perfectly practicable, and not only a saving of time and labour, but also doing away with the necessity of employing experienced ploughmen at high wages; as the machine can be easily controlled and guided by any man or boy of ordinary intelligence after a few lessons on its management. The cost, too, is not great, being about double that of the best iron plough now in use. It could be probably still further modified and cheapened by our own agricultural implement manufacturers.

It is Mr Rennie's intention, we believe, to import several more of them during the winter, and have them tested with the dynometer next year.

Shorthorn Sales in Britain

A number of recent sales of Shorthorns are reported in our English exchanges; among them the following are worthy of notice :—

A sale was held early in October of a selection from the herds of the Messrs. Garne, of Broadmoor and Churchill Heath, when no very high figures were given, but prices were pretty uniform, and the good average of £36 4s. 4d., on fifty-seven animals, was realized, the fifty-four cows and heifers making £36 2s. 11d. each.

A herd of 74, belonging to Mr. Butler, of Badminton, sold the next day, including some higher figures, but making much the same averages, namely, £38 7s. 4d. on the whole, and £39 11s. 7d. on 62 cows and heifers by themselves. Bids were made in several cases for Mr. Cochrane.

At the sale of Mr. Hewer, Sevenhampton, prices were low, averaging £26 on cows, about £23 on heifers, and less than £12 on calves. A fine lot of Berkshire pigs were sold at good prices, Mr. Beattie, of Canada, being one of the most liberal purchasers, and paying from 9 to 17 guineas each for a number of young sows. One young boar brought 21 guineas. The forty pigs realized £459 18s., or an average of £11 10s., said to be probably the highest price that has ever yet been realized for a similar lot of Berkshires.

A draft from the herd of Sir G. R. Phillips, Weston Park, was sold on October 18, consisting of 39 females and 9 bulls. The averages were very good, being £46 15s. 6d. on the former, and £28 on the latter, or £43 5s. on the whole 48. The highest prices paid were—£215 5s. for Polycherry, red, calved Sept, 27, 1868, by 3rd Duke of Geneva; £210 for Lactea Oxoniensis, roan, calved Jan. 27, 1867, by Imperial Oxford; £183 15s. for Lactine, roan, calved March 14, 1869, by 3rd Duke of Geneva, and £115 10s. for Polygeneva, calved March 29, 1869, by the same bull. As regards the several families of cows embraced in the sale, the following averages are given :—

		£. s. d.	Average. £. s. d.
13	Fawsley & Charmers	1099 16 0	83 16 9
12	Welcomes.....	365 8 0	33 4 4
6	Gwynetha	174 6 0	29 1 0
18	Shorter Pedigrees	446 15 6	24 16 5

At a recent sale of Mr. Marr's short-horns, Uppermill, reported in our English exchanges, the average price of twenty bulls sold was £25 14s.; the average price of heifers was over £26 10s.; and the total proceeds £1059 10s. Some of the lots were destined for Canada.

Cattle Plague.

For upwards of fifty years the continent of Europe has been a stranger to the wide-spread diffusion of cattle plague which now exists. The disease has extended far and wide from many of the places then named as centres of the infection. This was to be expected, seeing that the pressing necessities of war prevented the full adoption of those sanitary measures on which Central Europe mainly relies for arresting the cattle plague. Passing onwards with the German army, the plague soon came into the valley of the Marne and the Seine, and according to some reports has absolutely made its appearance in Paris itself. How it passed the Prussian lines which beleaguer the unfortunate city may not perhaps be known, although we can easily conceive of many ways by which the infection might easily be transmitted inside the fortifications. The provinces of Alsace and Lorraine—especially in the district around Metz—are sustaining severe losses; indeed it has been recently stated that the cattle were there dying too fast to admit of their proper burial. Around Metz also the plague has broken out among the sheep. To save as much food as possible the Germans are slaughtering the apparently uninfected animals, and salting down their carcases. In the Palatinate the plague is reported to exist in sixty communes, and already about 1,200 beasts have been killed to arrest its progress in the neighbourhood of Kaiserslantern and Landau. Fairs and markets are suppressed in Luxembourg, and also the herding together of cattle in large numbers belonging to different owners. In Rhenish Prussia the disease has broken out in the neighbourhood of Treves and Cologne, and also in some districts near Coblentz. In Prussia proper it has re-appeared in many places in which it

was thought it had been exterminated. Six places near to Potsdam, according to the latest intelligence, are still the seat of the malady. No improvement has taken place either in Pomerania or Mecklenburg. In the latter-named duchy the prevention of the pasturage of cattle in open fields, among other means of suppression, has been adopted. In Saxony no more cases are reported from Dresden; but Freiberg, Langenuime, and Berthelsdorf are still centres of the infection. In Poland also no improvement has taken place, while the spread of the disease in Galicia may be designated as most serious. Eight divisions of the country, some of which are far removed from each other, are now suffering from the cattle plague. In Transylvania the disease is on the increase. We have no information from Hungary; but in Turkey and along the Asiatic shore of the Black Sea the disease is far from being exterminated.—*Mark Lane Express.*

Ploughing Match.

A ploughing match for the Township of Hamilton was held on the farm of Mr. Wm. L. Burnham (Lot 25, in the 1st Concession), on Tuesday, the 15th November, when thirty ploughs entered for the match. They were divided into three classes, two for men according to the kind of plough used, and one for boys. There were eighteen in the first class, seven in the second, and five in the boys' class. The rain of the previous day had made the ground rather soft, yet the work was all well done, and some of the boys' ploughing was particularly good. The Judges, Messrs. Wm. Mulholland, George Carruthers, and John Kendall, after long and careful examination, awarded the prizes as follows, viz. :—First class: 1, Geo. Retalick; 2, — Wright; 3, Patrick Doyle; 4, James Raby; 5, William Smith. Second class: 1, Matthew Smith; 2, Robt. Ferguson; 3, David Buttars; 4, Walter R. Riddell; 5, William Mason, junior. Third class: 1, George Farr; 2, Samuel Redpath; 3, Francis Ward; 4, James McCulloch; 5, David McIntosh. The day was fine, and there was a large number of spectators from Hamilton and neighbouring townships, and much interest was taken in the work as it progressed. It was the largest ploughing match, we believe, ever held in the township.

The rinderpest continues to make frightful ravages among cattle around Metz and other parts of France and Germany.

The Western Fair Committee of London have met and reported a successful financial result. The Fair of 1870 has sustained itself, with a little to the good. With the untouched fund in 1868 of $1,000, and $2,500 of the city society in the bank, the directors of the institution congratulate themselves upon having $3,500 as a capital to start with next year.

One of the novel and attractive features of the California State Fair at Sacramento, was the display of indigenous sugars, of which there were specimens manufactured from beet-root, and also from melons.

"Free markets, free roads, no tolls," is the cry in Kingston. The loss of the military is stirring up the people to counterbalance it by attracting produce to the city from the back country to a free market over open roads.

The exports from the port of Napanee to the United States for the month of October were 174,960 bushels of barley, 1,015,300 feet of lumber and other woods, amounting in all to $155,066.

The Waterloo cattle fair on the 8th Nov., was attended by about 100 head of cattle. From 3½ to 4 cents per lb., live weight, were the ruling figures for those in moderately good condition. There appeared to be a lively demand for cattle for feeding purposes.

A Bee-keepers' Convention is to be held in Cincinnati, Ohio, on Wednesday and Thursday, February 8th and 9th, 1871, at which all sections of the United States, Canada, and other places, are to be represented.

In New York and some other American States a very commendable law is in operation, by which any one who plants shade or fruit trees on the highways is relieved from his assessment of taxes to the extent of $1 for every four trees so planted at distances specified by the Act.

A Fish-breeders' convention has been called to meet at the Skating Rink, New York city, December 20. A show of fish may be expected in connection with the exhibition of the New York State Poultry Society. The design of the convention is consultation for the protection of the interests of fish breeders, and, if thought best, to organize a permanent association.

The Elora *Times* says there have arrived at the Elora railway station during the past week about seventy car loads of wheat. The wheat was purchased in Milwaukee by J. M. Fraser, Whitlaw & Gay, and J. M. Ross; and after paying expenses of freight, &c, can be laid down at their mills cheaper than they can purchase it from the farmers around Elora.

The report of the United States Department of Agriculture comes to the startling conclusion that such is the wholesale destruction of American forests, there will be an actual famine for wood in the country within thirty years, unless immediate measures are taken to supply their places by new plantations. It is estimated that from 1850 to 1860, 20,000,000 acres of timber land were brought under cultivation, and that in the present decade no less than a hundred millions will be so reclaimed. We see but one remedy for this :—Let the Government offer large premiums for the cultivation of forests.

It is said that the English sparrow is death on the curculio and the caterpillar, two great pests to fruit trees. The English sparrow is found to be easily acclimated in Canada, and the colony in Quebec is thriving heartily. Following the example of Colonel Rhodes, of Quebec, Mr. John Proctor, of Hamilton, intends to bring with him on his return from England a large number of these birds, which will be turned loose in the spring.

Owing to the letting of two of the Branches Park farms, and the consequent necessity of the reduction of stock, a portion of Lady Pigot's herd of Short-horns was lately sold. Among the cows disposed of, Mantalini 2nd brought the highest price, 260 guineas; 100 guineas was given for La Belle Heleue, 80 for Lady of Branches, and 75 for Pelo. The other cows made from 22 guineas to 56 guineas each. Several young bulls were subsequently offered, but none of them made more than 31 guineas. The total produce of the sale was £1,179 18s. for thirty head; the average obtained per animal offered was £39 5s.

MR. BEATTIE'S IMPORTATIONS.—We learn that Mr. Simon Beattie, who now resides near Bangor in Pickering, besides his valuable services in selecting stock for Mr. Cochrane, has recently imported on his own account several short-horns of great beauty and high pedigree. Among them is the cow Innocent, a fine looking animal of large size, the dam of some excellent stock in England, and descended from Mr. Robert Collins' Cowslip, the ancentress of the celebrated prize heifer Countess of Yarborough, winner of premiums at the Royal and Yorkshire shows. Mr. Beattie has also imported two bulls, Bothwell, 25661, and Lord York, 26766. The latter is half-brother to Mr. Cochrane's renowned heifer Duchess 97th, both having been sired by Captain Gunter's Third Duke of Thorndale. A very superior entire colt, a Cleveland bay bred by Mr. Bruere, of Braithwaite Hall, Yorkshire, also came out by the "European" for the same enterprising importer.

Farmers in the burnt Ottawa district are setting to work vigorously to repair their losses by the disastrous fires of last summer. The Ottawa *Citizen* says that in some places they have adopted the plan of entering into partnership to cut and draw fence stuff for their farms with one team, and send their idle horses to the shanties. They are enabled in this manner to keep their teams for next spring's work and draw timber enough during the winter to rebuild their fences when the snow is gone. The horses in the shanties will be earning money to purchase feed to keep them from the time they leave the shanties in the latter end of the winter until the grass is good. They would feel a great loss in the spring if they should be compelled to part with their teams this fall through want of the means for keeping them through the winter.

Miscellaneous.

Bear-hunting Extraordinary.

In the fall of 1842, I was engaged in inspecting some lands in the township of King, then almost a wilderness in comparison with what it is now. Wild animals were comparatively numerous, bears and wolves especially. One wet evening I stopped at a newly-erected farm house, occupied by an old English family, who had moved on to the land about two months previously. The house was not even chinked or plastered, and great difficulty was experienced in keeping the candles burning, on account of the wind. The settler, who had determined to make his home in Canada, had brought everything he could with him from England, and amongst the rest the ancient family "spit." To the uninitiated, we must explain that the old English spit, now long banished from modern households, was formed of a bar of steel half an inch thick by one and a quarter inches wide. There was a formidable spear-shaped point at one end, whilst the other was terminated by a strong oak wheel, two inches thick and about eight inches in diameter.

About two feet from the north side of the house was the pig-pen, formed of upright rails set firmly into the earth, and built in this fashion to protect the grunters from a bear that had regularly visited the farm for some days previously, and generally had succeeded in carrying off a young half-grown pig, or severely injuring it. Between the house logs and the rails of the pig-pen there was a sort of stile built of cross rails, about two feet long, and this stile thus formed was about three feet high, and intended as a defence to the passage of the pigs during the day, from their yard to the garden.

Just after our supper, composed of potatoes and milk, was over, the same ominous sounds which had accompanied the bear's former visits were quite audible. He had found out the new pig pen, and was walking round and round it, seeking, as usual, to get one of the inmates. The pigs were in an awful fright, grunting and running about their enclosure, and endeavouring to escape, whilst Bruin would every now and then dash his paw through the rails in his efforts to catch hold of a pig. No doubt, a few previous or present scratches added to the general tumult amongst them

The old farmer, who was no hunter, did not know what to do. The bear kept running round the pen, and each time clambering over the stile, quite close to us, and at last determined to use the elevation thus obtained to clambor over the enclosure. The old wife, thus seeing the certainty of ultimate success on the part of the bear, who by this time, with the excitement of the chase, had ceased to pay any attention to us, although sometimes within four feet of us, now became thoroughly roused, and after reproaching her husband and your humble servant for their pusillanimity—and truth to tell she was an awful scold—seized the aforesaid spit, and when the bear next clambored over the stile, she, with a furious exclamation, plunged the weapon into, and about two feet completely through the bear, and about one foot into the pig pen, between the upright rails. The stab was given with a right good will, and the spit driven quite through as far as it would go, accompanied with the usual English expletive of "Drat you, you brute!" and the bear being absolutely transfixed with the spear end of the spit through the rails of the pen, and the other end prevented from being pulled through the logs by the wheel before mentioned, the bear was thus entirely powerless for mischief. He was not killed outright, nor, indeed, so far fatally wounded as to make him quiet. Of course he would have died, but not from the instant effects of the wound. The consequence was that he became furious, and tore about in a frantic manner.

When we found the animal absolutely incapable of resistance, we sallied out, and finished his career with the axe. We feasted from his meat that night and next morning for breakfast. Our former diet of potatoes and milk was entirely thrown in the shade by this wholesale importation of bear meat.

Some may doubt this little anecdote, but it is literally true, and the old man retained the bear skin for many years, and used to boast of his wife's prowess. She, in her turn, certainly used often to jeer at his want of presence of mind, and this little episode formed the source of many an evening's tale.

C.

Tanning Sheep Skins.

The following directions for tanning sheep skins, which we take from the *Prairie Farmer*, will be useful to some of our readers:

For mats take two long woolled skins, make a strong suds, using hot water; when it is cold, wash the skins in it, carefully squeezing them between the hands to get the dirt out of the wool; then wash the soap out with clean, cold water. Now, dissolve alum and salt; half a pound, with a little hot water, which, put in a tub of cold water sufficient to cover the skins, and let them soak in it over night, or twelve hours; then hang over a pail to drain. When they are well drained, stretch or spread carefully over a board to dry. When a little damp, have one ounce of saltpetre and alum, pulverized, and sprinkle the flesh side of each skin, rubbing in well, then lay the flesh sides together, and hang in the shade for two or three days, turning the under skin uppermost every day until perfectly dry. Then scrape the flesh side with a blunt knife, to remove any remaining scraps of flesh, trim off the projecting points, and rub the flesh side with pumice or rotten stone, and with hands; they will be very white and suitable for a door or carriage mat. They also make good mittens. Lamb skins (or sheep skins, if the wool be trimmed off evenly to about one-half to three-fourths of an inch long), make most beautiful and warm mittens for ladies or gentlemen.

A Model Tool House.

"Where shall I find a blacksmith?" said a traveller in a frontier settlement to an individual whom he met on the road. "My horse has lost a shoe, and I wish to have it replaced." "I am a blacksmith," replied the person addressed. "But where is your shop?" "This is my shop," said the son of Vulcan, with a graceful sweep of the hand such as Selkirk may be supposed to have made when he exclaimed, "I am monarch of all I survey;" "this is my shop, but my anvil is a mile ahead."

Almost as extensive as this frontier blacksmith's shop is the tool house of neighbour P. The blue heavens above are its roof; that portion of mother earth included within the boundary fences is the floor, and each field is a compartment. In each compartment may be found one or more farming implements; here a plough standing in the furrow where it was last used; there a harrow gracefully reclining against a fence; cultivators, reapers and mowers, and grain drills basking in the sun; hoes, scythes, grain cradles, rakes, etc., hanging on the trees and fences, whilst about the barn are conveniently congregated rollers, carts, waggons and other implements "too numerous to mention." Neighbour P. is an ardent admirer of the good old adage, "a place for every thing, and every thing in its place."—*Cor. Country Gentleman.*

Mechanical Items.

Horse-chestnut has great lasting qualities when exposed to moisture, and might be made useful for mill work.

TO CLEAN STONE.—Boil a pound of pipe-clay in three pints of water and a quart of vinegar; put in a bit of stone blue. Wash with this mixture, and when quite dry, rub with a dry flannel and a brush of moderate stiffness. Sweep off the fine dust thus raised with a clean hand-brush.

GRINDSTONE SHARPENING.—A correspondent of the *Scientific American* says:—"The grindstone is a self-sharpening tool, and after having been turned some time (if a hard stone) the motion should be reversed. Sand of the right grit applied occasionally to a hard stone will render it quite effectual.

SELECTING GOOD OAK.—When selecting this wood for whippletrees, &c., choose that

in which the concentric rings are close, thick, and uniform, and has, when cut, a glossy varnish-like appearance, and is of a pale yellow or straw-colour. That which has a bluish tinge is generally tough, but is apt to be elastic or springy.

STEEL DRILLS.—A mechanical journal says that drills should be made as short as the work to be done will allow. Much care is required in hardening them, as it is a very easy matter to make them too hard, or to overheat the steel. After the proper temper is obtained draw the temper a little above the point, and there will be less danger of the drill breaking. Do not use oil as a lubricator when drilling steel; water is much better. All that is required is to keep the drill cool.—*Ohio Farmer.*

To Prevent Decay of Shingles.

The following is said to effectually prevent decay in shingles: Take a potash-kettle, or large tub, and put into it one barrel of lye of wood ashes, five pounds of white vitriol, five pounds of alum, and as much salt as will dissolve in the mixture. Make the liquor quite warm, and put as many shingles in it as can be conveniently wet at once. Stir them up with a fork, and when well soaked, take them out and put in more, renewing the liquor as necessary. Then lay the shingles in the usual manner. After they are laid, take the liquor that is left, put lime enough in it to make white-wash, and if any colouring is desired, add ochre, Spanish brown, lamp-black, etc., and apply to the roof with a brush or old broom.

This wash may be renewed from time to time. Salt and lye are excellent preservatives of wood. It is well known that leach-tubs, troughs, and other articles used in the manufacture of potash, never rot. They become saturated with alkali, turn yellowish inside, and remain impervious to the weather. *Ohio Farmer.*

HOW TO GUARD AGAINST DROUGHTS.—A Central Illinois correspondent gives, in an American paper, the following means of guarding against the worst effects of drought: 1. Underdraining, trench ploughing, or ploughing 6 or 7 inches deep. 2. Fall ploughing, or where that has not been done, ploughing as early as the last half of March. 3. Sowing and planting, if not in March, at the earliest practicable hour. 4. Sowing and seeding thinly, and clean and careful system of cultivation.

The rise in the value of farm property has been very general in all parts of Canada for a few years past, but the Chatham *Planet* says the county Kent has far outstripped any other section, now that the fame of "the Garden" has been spread abroad. Farms which might have been bought a few years ago for $10 or $15 an acre, have now doubled in price, and it is no uncommon thing to hear of sales of choice farms at $30, $40, and even $50 an acre. A few days ago Mr. Wm. Williams sold his farm in Dover, (124 acres) about three-fourths of a mile down the river, for the enormous sum of $9,000. The purchaser is Mr. Pullar, at present residing on the mountain near Hamilton. South of the river the Southern Railway is affecting the prices of farm property very materially, but the figures asked are by no means exorbitant.

DOMINION OF CANADA

V. R.

EMIGRATION

TO THE

PROVINCE OF ONTARIO.

To Capitalists,
Tenant Farmers,
Agricultural Labourers,
Mechanics,
DAY LABOURERS,

And all Parties desirous of Improving their Circumstances by Emigrating to a New Country.

THE attention of intending Emigrants is invited to the great advantages presented by the Province of Ontario. Persons living on the interest of their money can easily get eight per cent. on first-class security.

Tenant Farmers with Limited Capital

Can buy and stock a Freehold Estate with the money needed to carry on a small farm in Britain. Good cleared land, with a dwelling and good barn and outhouses upon it, can be purchased in desirable localities at from £4 to £10 Stg. per acre. Farm hands can readily obtain work at good wages. Among the inducements offered to intending Emigrants, by the Government, is

A FREE GRANT OF LAND

(WITHOUT ANY CHARGE WHATEVER.)

Every Head of a family can obtain, on condition of settlement, a FREE GRANT of two hundred acres of land for himself, and one hundred acres additional for each member of his family, male or female, over eighteen years of age.

All Persons over 18 years of age can obtain a FREE GRANT OF 100 ACRES.

The Free Grants are protected by a Homestead Exemption Act, and are not liable to seizure for any debt incurred before the issue of the patent, or for twenty years after its issue. They are within easy access of the front settlements, and are supplied with regular postal communication.

Registers of the Labour Market

And of Improved Farms for sale, are kept at the Immigration Agencies in the Province, and arrangements are made for directing emigrants to those points where employment can be most readily obtained. Several new lines of railway and other public works are in course of construction, or about being commenced, which will afford employment to an almost unlimited number of abourers.

Persons desiring fuller information concerning the Province of Ontario, are invited to apply personally, or by letter, to the Canadian Government Emigration Agents in Europe, viz.: Wm. Dixon, 11 Adam Street, Adelphi, London, W. C.; J. G. Moylan, Dublin; Charles Foy, Belfast; David Shaw, Glasgow; and E. Simaya, Continental Agent at Antwerp.

Also to the Emigration Agents in Canada, viz:

John A. Donaldson, Toronto; R. H. Rae, Hamilton; Wm. J. Wills, Ottawa; Jas. Macpherson, Kingston; L. Stafford, Quebec; J. J. Daley, Montreal; E. Clay, Halifax, Nova Scotia; Robert Shives, St. John, and J. G. G. Layton, Miramichi, New Brunswick, from whom pamphlets issued under the authority of the Government of Ontario, containing full particulars in relation to the character and resources of, and the cost of living, wages, &c., in the Province, can be obtained.

JOHN CARLING,
Commissioner of Agriculture and Public Works for the Province of Ontario.

Department of Immigration,
Toronto, October, 1869. v2-2-12t.

TO AGRICULTURAL SOCIETIES AND BREEDERS.

For Sale or Hire,

One of these magnificent, high-stepping, powerful and active Cleveland Bay Coaching or Roadster Stallions, six years old, about 16 hands 2 inches high, imported October last by O. E. TEASEL, to whom apply, or to H. PRETTY, Belleville, Ont. v2-12-1t

Sale of Thorough-bred Stock

THE UNDERSIGNED

Will Sell By Auction,

At his Farm in Markham,

On the 18th day of January, 1871,

A very superior lot of Thorough-bred Stock, consisting of 6 Pure Short-horn Bulls, and 14 Short-horn Cows and Heifers, besides a number of very fine Grades.

GEORGE MILLER,
v2-12-1t *Markham.*

Markets.

Toronto Markets.

"CANADA FARMER" Office, Dec. 13th, 1870.

FLOUR AND MEAL:

The produce market generally, owing to the close of navigation and the interruption in the cable reports, has been unusually dull. But few sales have been effected. The following are the quotations:—

Flour—Superfine, $5 00 to $5 25; Fancy, $5 40 to $5 50; Extra, $5 75 to $6 00.

Oatmeal—$5.25.

Cornmeal—$4.00 to $4.75.

Bran—$15 per ton.

GRAIN AND SEED.

The market, from causes already mentioned, has been extremely quiet with very few transactions beyond the supply of mere local demands.

Wheat—Soules, $1 20 to $1 23; Spring, $1 12 to $1 15.

Barley—No. 1, 60c to 63c; No. 2, 50c.

Peas—68c to 71c.

Oats—45c to 46c.

Rye—70c.

Clover Seed—$5 50 to $5.

Timothy—$2 50 to $3.

HAY AND STRAW.

Hay—Owing to the state of the roads, receipts have been light, and the price is higher—selling at from $12 to $16.

Straw—Scarce—from $12 to $14.

PROVISIONS.

Live Hogs—5c per lb.

Dressed Hogs—6c to 6¼c per lb.

Beef—From 4c to 6c per lb.

Mutton—From 5c to 6¼c per lb.

Poultry—Turkeys from 50c to $1; Geese, 45c to 60c; Ducks, 50c per pair; Chickens, 25c to 40c.

Eggs—20c to 25c per dozen.

Bacon—9c to 9¼c.

Hams—12¼c to 13¼c.

Lard—12c to 13c.

Butter—18c to 20c.

Hops—13c.

Salt—Goderich, $1 00; American, $1 85; Liverpool, per bag, 75c.

HIDES AND SKINS.

Hides—7c to 8c.

Sheepskins—30c to $1.

Calfskins—Scarce; nominal at 12½c to 13c.

CATTLE MARKET.

Beeves from 3c to 5c per lb.

Sheep—$3 to $5.

Lambs—$2 50 to $3 50.

Calves—Scarce; from $5 to $10.

London, Dec. 6.—*Spring Wheat*, $1 15 to $1 27. *Red Fall Do.*, $1 10 to $1 15; *White Do.*, $1 to $1 28. *Barley*, 48c to 56c. *Peas*, 65c to 70c. *Oats*, 41c to 42c. *Corn*, 70c to 75c. *Rye*, 40c to 50c. *Dressed Hogs*, $6 25 to $6 65. *Hay*, $8 to $11. *Timothy Seed*, $2 50 to $3. *Potatoes*, 35c to 45c. *Turnips*, 15c to 20c. *Fleece Wool*, 28c to 31c. *Eggs*, 20c to 23c. *Butter*, rolls, 17c to 22c; do., tub, 12½c to 18c. *Cheese*, factory, 10c to 11c: do., new, 8c to 10c. *Onions*, $1 to $1.12½c. *Tallow*, 6½c to 7c. *Green Hides*, inspected, No. 1, 9c.

VOL. III. No. 1. TORONTO, CANADA, JANUARY 16, 1871. NEW SERIES.

The Field.

Winter Work on the Farm

The principal work of the farmer during the long, and comparatively leisure season of winter, should mainly be directed towards accumulating a supply of plant food for the next season's crops. Everything that can possibly be done in the way of adding to the manure heap the progressive farmer will aim to accomplish. Swamp muck should be dug out wherever it can be had, and drawn to some place near the barnyard where it can be readily available to use as an absorbent and retainer of the salts contained in the liquefied portions of the manure. If muck be dug and exposed to the air for a year before being added to the manure heap, it will become much more valuable from being dried and partly decomposed. Where it can be had in sufficient quantity, muck often proves a valuable top-dressing to meadows. It can be spread over them any time during the winter, and, though no immediate benefit may result to the hay crop that year, yet as soon as the action of atmospheric agents has so far decomposed the material contained in the muck, which is principally organic vegetable humus, and the plants can eliminate their food from it, a very great improvement will take place in the meadows top-dressed with the muck. This does not usually occur till the second season after the muck is applied, unless it is first decomposed by previous exposure for one season before being spread on the land. The amount of dressing to be applied will depend upon the state of the soil of the meadow. If it be deficient in vegetable matter, one hundred two-horse waggon-loads of muck to the acre will be none too much. Usually, however, half that quantity will be sufficient.

If leached ashes can be obtained within a reasonable distance, all that can be had should be drawn to the farm, and applied as a top-dressing, at the rate of from thirty to fifty waggon-loads per acre, to those portions that appear to be deficient in those salts of which potash is a base. To the clover crop this dressing is especially valuable, and it may be combined with muck to advantage, and plaster afterwards sown on the land, when the clover is well forward in spring.

Every available load of stable manure that can be had from the town or village nearest, or from any hotel in the neighbourhood, should be bought up and brought to the barn-yard, where it should be properly composted before being spread on the land, in order to destroy, as much as possible, the vitality of the seeds of noxious weeds and plants that may have found their way into it. This should be well attended to, otherwise much trouble and loss may result from the too common practice of applying such manure directly to the land, to save the trouble of twice loading and unloading it. Most of the hotels and townspeople who keep horses or cows are usually glad to make an arrangement with the farmer, to give him all the manure made, in exchange for his supplying them with straw for stable bedding; and where this is done the farmer can insure the manure being tolerably free from foul seeds, by supplying only straw from clean crops.

STOCK.—Every animal on the farm should be well looked after during the winter, and care taken that each gets its full allowance of the food given out. Where all are stabled, this is an easy matter, but where they run together in the yard or sheds, the weaker ones often suffer greatly for want of sufficient food, the stronger ones taking more than their share. If the animals have commenced the winter in good thriving condition, their thriftiness is the more easily kept up, but once they lose flesh during cold weather, it becomes somewhat costly and difficult to make them regain it, as an animal in poor condition can rarely be induced to eat and digest more than will go towards keeping up its animal heat while the cold weather lasts.

We are inclined to think large troughs or boxes better than overhead racks for feeding out hay to stock. One great advantage they possess is that they prevent much waste, for an animal eating out of a trough or box rarely takes up more than a mouthful at a time, and eats it up before taking another, while it may often be noticed that when they feed at racks they will pull out much more than they can eat at once, drop a portion at their feet, and trample it in their effort to reach up for the next mouthful. They keep always putting their heads up to the rack, leaving untouched what has dropped before them. If troughs are used they should have high [illegible] them, to catch the waste and [illegible] of hay, which usually consists [illegible] nutritious portion.

Of course all their feed can be cut up, so much the better, and the saving of waste alone in this case will more than repay the farmer for the extra labour of cutting. The cut hay being usually given in troughs or boxes, it is seldom a particle is lost. No pains should be spared to see that all the stock obtain a regular supply of water. If they have to obtain it at a pond or creek, enough holes must be cut in the ice, when it forms, for every animal to obtain a supply without crowding; or what is better, a boy should go with them to the water and see that the older and stronger ones do not monopolize the watering place for hours at a time, while the weaker and younger ones wander away in search of it at some other place.

Animals that are being fed up for the butcher need every care and attention. Regularity in the hours of feeding is of the greatest importance, if we wish to fatten an animal. The food must be so regulated that they will keep constantly gaining in condition without becoming really fat, until near

UNIVERSITY OF TORONTO SEP 7 1954

the time when they can be sold to the most advantage, which is usually about Easter. A month or six weeks before that time, the process of forcing them into fatness by giving stimulating food, such as grain or oilcake, should begin. In Britain, much use is made of certain artificial compounds, called cattle foods, which are given sparingly as an addition to their ordinary feeding stuffs in order to excite their appetite, and induce them to fatten faster, by more largely consuming of what is set before them. Every pound of food an animal can eat beyond what is required for the system goes to make fat.

Let the stables and byres be kept as clean and well aired as is compatible with the comfort of the animals. See that the cattle do not get their skins full of lice or scurf, or become hide-bound. Any animal affected in that way must be taken away from the others, and kept isolated till cured, otherwise the contagion will spread throughout the whole of the stock, and entail a heavy loss to the farmer through the rapid falling-off in condition and thrift thus produced. It is easy to prevent skin disease by keeping the animals thrifty and clean, using a curry-comb occasionally on the hide; but once they become affected, it is often exceedingly difficult to get rid of the trouble.

In feeding grain to horses or cattle it will be found by far the best plan to feed the grain crushed rather than whole. The charge made at the mills for crushing coarse grain is, however, in our opinion, altogether too high; besides the loss of time in going to and from the mill. In Britain they avoid this by using hand machines, that do not grind the grain, but simply bruise it in such a way as to make it readily acted upon by the gastric juices of the animal's stomach, and therefore easily digestible. These mills are portable, and easily worked by either horse or manual power, according to size. Such machines would prove a valuable acquisition on most farms where stock is to be fed for the butcher, or many horses or cows are kept.

PREPARING SEED GRAIN.—Every care should be taken to select the best and most profitable varieties of grain for spring seeding, whether for home use or sale. Next, the seed to be sown should be well and thoroughly cleaned, so as to be free from foul seed of every sort, and be put away where it will not be likely to be meddled with. The best way to do this is to put it in clean barrels—empty apple barrels will do—and head each down tight, writing the name of the grain or variety on each in pencil, and set them away where they will keep dry and sound. To keep the rats from eating holes in the barrels, strew some inferior loose grain on them, or keep some in an open box in the place where they are stored away.

GRASS SEEDS.—Much can be done to improve our meadows, if great care be taken to obtain only perfectly clean samples of clover and other grass seeds. Much of the timothy seed obtained this year is very foul, and great care is needed to have what is to be used properly cleaned before sowing, which can only be done by hand sifting through fine sieves.

Beet Root and Beet Root Sugar

NO. IX.

The object of the papers which have been written on this subject has been to "popularize" the idea that beet root sugar can be produced in Canada, as well as on the continent of Europe, and on the Canadian farm as as an ordinary practical industry of our yeomanry; and this object, it is gratifying to learn, has been thoroughly accomplished Both the editor of the CANADA FARMER and the writer of these papers have received numerous enquiries which show that a firm hold has been taken by the Canadian mind on the subject. Parties at Toronto, Guelph, Elora, the county of Waterloo, and the neighbourhood of St. Thomas, and in numerous other places, are forming themselves into incipient Beet Root Sugar Companies, all eagerly looking for information on the subject, and prepared to act as soon as they are sufficiently informed concerning it, and can obtain skilled labour, or chemical assistance to carry their proposed works into effect. To all such we say, avoid all those, except practical chemists of first-rate standing, who have been used to the old-fashioned, cumbrous, continental system—those who talk of requiring from sixty to one hundred thousand dollars' worth of machinery to begin with; and above all, avoid all "mystery men," who nod and wink and "talk cunning," who say what they can do, but will not tell how they do it, and who claim a sort of divine right over the manufacture, whether in growing the root, or making the sugar. Depend on it, any man who is fit to be trusted with the manufacture will tell his employers not only what he can do, but how he does it. Superior skill will in this, as in all other businesses, command ample remuneration, without the necessity, on the part of the practical manager, of hiding from his employers his processes, and pretending that no one can master them but himself.

The latest discoveries in the art of the growth and manufacture of beet root sugar have wonderfully simplified the process, and these have finally resolved themselves into the best mode of manufacturing, from the juice of the beet root, "Sucrate of Lime."

This, according to the latest English work, is prepared as follows: It has been a fact long known to chemists, that all the alkalies have a special facility, under certain circumstances, of combining with sugar; and of the alkalies, lime, from its cheapness and convenience, is the one best adapted for the use of the manufacture of sugar, whether produced from the beet, the sorghum, or the sugar cane. When a syrup of from 30° to 32° Baume (about as thick as medium maple molasses) containing either sugar or sugary substances, is kept in motion, and carefully slaked and powdered *quick* lime is scattered over its surface, in such a manner as by motion to be easily mixed through the solution, it unites with the sugar of the liquid, and forms a mass more or less insoluble, which, on rest being given, falls to the bottom of the vessel, and is the "sucrate of lime." The lime being dispersed through the syrup containing sugar and other matters, searches for and takes up the sugar of the liquid, and unites with it; but it does not unite with the other matters in the fluid, or, at all events, not in a degree to be mischievous. All the mischievous elements in the beet juice—for instance, such as common salt, potash, the strong taste of the beet root, which consists of a chemical element called "betain," the earthy bitter matters, and in fact, everything but the sugar—remains in the liquid which deposits the sucrate of lime, and which liquid, after the sugar is all extracted, may be fermented for spirit, or run off to the manure heap, to which it forms a most valuable addition, and the resulting sucrate of lime remains in a state more or less pure, according to the process which has been made use of, and the skill and care with which the substance has been formed. This sucrate of lime (we condense from the same work) is always made in syrup which is either cold or only slightly warmed. When formed, it is unalterable, either by time, fermentation, insects, mildew, or the action of the atmosphere. It may be shovelled out on a floor, and allowed to drain dry, or it may be dried by artificial heat. As you make it, so it remains unchanged and unchangeable, except by the "carbonatation" process, which will be hereafter fully described, and which again separates the sugar and the lime.

Sucrate of lime is absolutely insoluble in boiling water, although partially soluble in warm or hot water; therefore it can by washing be brought to a state of great purity, and one that, on carbonatation, as hereinafter described, will produce pure refined sugar at once. This cleansing process is attained by the sucrate being washed in boiling water; thus, after it is first obtained, and the dirty liquor run off, more water should again be added, again boiled, and again run off, until it comes off colourless. Or the sucrate may be washed on a filter until cleansed, but the washing process must always be conducted whilst the water is within a very few degrees of boiling heat, and it always ought to be done at 210 to 212 degrees by the thermometer—Fahrenheit.

For the same reason, the resulting liquor in which the sucrate of lime was formed should always be boiled, and allowed to settle before it is run away, because you in this manner obtain a considerable portion of the sucrate which was either dissolved in the original liquor or else was floating in it in an unsuspected shape, for any part of it which may be dissolved at a lower temperature is again rendered insoluble by a boiling heat. As soon as the liquid, however, reaches the boiling point, the whole of the sucrate is deposited, and the liquor only contains the impurities.

Sucrate of lime thus made contains in its first wet state from 37 to 40 per cent. in weight of water. Of this water 27 to 30 per cent. drains away or dries out by the action of the air, and the dried residue consists of 66 per cent. of sugar, 20 per cent. of lime, and ten per cent. of water, which being a water of hydration, it does not part with at ordinary temperatures. Recollect that this is *pure sugar*. There is no molasses or other uncrystalizeable matter in it. If you find such, on finally reducing it to sugar, you have made them by imperfect manipulation; they did not exist before.

This sucrate of lime may be stored in bins, barrels, or bags. It can be put by with safety until the season of the year, leisure time, or other circumstances enable the farmer to reduce it to sugar; or it may be carried to the refinery or exported abroad. It is an article (when well and carefully prepared) containing a fixed and certain amount of pure sugar, and is of a fixed and certain mercantile value. It is not destructible either by the influence of time or climate. It is simple in its preparation and the process is easily understood, not being so difficult as the manufacture of butter, cheese, soap, or other home productions of a like nature. All its results are of use: the mother-waters contain and carry all the mineral matters, and with the result of the feeding pulp will, when properly applied, keep up the fertility of the farm unimpaired, and indeed add to it most profitably in the assistance such manure will give to future crops, both of beet, grain, grass and roots.

It will thus be seen that the first thing to be studied is the manufacture of sucrate of lime; that well understood, gives the key to success in the manufacture of beet root sugar on the farm. Anyone may, and all who intend to go into the manufacture of beet root sugar must, make themselves master of the best mode of manipulating this article. It signifies little whether, for practice, it is made out of beet root, or from coarse or fine cane sugar, molasses, or maple sugar, anything that contains crystalizable sugar will, when properly mixed with quick lime, yield sucrate of lime, and sucrate of lime when reduced by carbonatation will yield pure sugar. The carbonatation process will be the subject of a future article.

In the mean time, let every one who feels an interest in the matter get beet root, or even mangel wurzel if they cannot get beet. Reduce it to a pulp, and get out the juice, or, if they have no means of doing this, slice the roots into the thinnest possible shavings, soak these shavings in water at about 160 degrees of heat; this will extract the sugar and other soluble matters; as soon as the resulting liquor has been sufficiently boiled down and gets cold or cool, add powdered quick lime until the sucrate is formed. When this process is completed, take the resulting sucrate away, and boil the liquor in which it was made, let the sucrate subside, and draw off the liquor; then add (but always at a boiling temperature) water, and wash the sucrate until it yields no more colour and becomes clean. Prepare this substance twenty times, or until the process is familiar, and all changes are noted and understood; put by the results, and finally carbonate them, and you will then get the pure sugar, or at all events the pure syrup.

You can do all this in pots or saucepans, or the ordinary kettles or boilers of the farm; when you have mastered this process, you will be fit to operate on a mercantile scale, and then you will begin to be able, at a profitable rate, to procure beet root sugar.

NO. X.

Another matter, and which, perhaps, would have come in better before the last paper, on the sucrate of lime process, is the latest discoveries and improvements in evaporation of both cane and beet juice for the manufacture of sugar. This improvement has been forced on the attention of the producers of sugar from the fact that the refiners prefer a concentrated or inspissated juice of either plant, even though it contains all the natural impurities (provided the concentrated juice is not burned or browned), to ill-made, or, indeed, to ordinary well-made browned or crystallized raw sugar. The refiners can deal with the natural impurities better than they can with the destroyed or injured sugar which has been prepared by the ordinary method of boiling down in deep evaporating or defecating vessels. The following is the plan, and it seems to have been in a great measure borrowed from the American instrument for the preparation of maple and sorghum sap, only carried out to a greater length, and made continuous in its operation. By this means all scouring and fermentation of the juice is avoided, as the juice is evaporated as it runs from the mill or press.

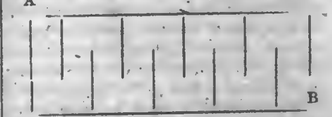
For a large concern, capable of doing about half-a-ton per hour, or thirty hogsheads in the course of a week, of six working days of ten hours per day, the description is given in nearly the following words:—

The machine is called "the concretor," and its object is to evaporate as nearly as possible to perfect dryness large masses of juice in the shortest possible time and at the least cost of fuel. A simple illustration of the way in which this is accomplished may be seen in the effect of throwing a pint of water upon a stone pavement, or even on boards exposed to wind and sunshine: every drop of the water will be dried up long before the same quantity could be boiled away in a small deep pan, even on a very hot fire, and yet no particle of the water would at any time have been hotter than the warmed flags or boards.

The machine consists of three principal parts—the tray, the cylinder and the drum.

1st. The tray is placed as close as possible to the grinder and press, and receives the juice direct from the latter. The tray is of cast iron, 30 feet long and 6 feet wide, and about 6 inches deep. It is crossed by ribs or ledges, which run from one side nearly to the other, the vacant space being on alternate sides of the tray It is not cast in one piece, but in several, which are joined together. They can, of course, all be made from one pattern, and made to join with screw-bolts and nuts, so that it can be lengthened if required, or any part broken can be replaced.

The accompanying figure may serve to give a notion of it. It can be made of greater or less length to suit the size of the purposed works, although we think the length in all must be the same, and the capacity be governed by the width.



This tray is set up at a gentle slope, so that the juice received in its upper end at A flows in a continuous stream of not more than about half an inch deep, backwards and forwards from side to side, to the lower end B. The whole length of the passage in the machine, reckoning it in the length of the course of the liquor, is 140 yards.

This tray is set flat upon two walls of brickwork, and the firing takes place under the tray at A, while the flame and smoke of the fire pass to the other end, and are carried off by the chimney. (In the American plan the entire tray and fireplace and chimney are constructed of sheet iron, and the whole stands on two rockers, so that by raising either end the attendant can hasten or retard the flow of the liquor as he may think necessary.) The flame of the furnace spreads evenly along the bottom of the tray, being confined by the brick walls, and the draught is perfectly clear and uninterrupted. The time occupied by the passage of the juice through the tray, in its serpentine course, is about five minutes, in which short period eleven-sixteenths of the water are driven off, and the juice has become *siting* It will thus be seen that the first rash heat of the fire is applied to the thin juice,

whilst in rapid motion, and while it is so thin and liquid that there is no fear of burning, and as it becomes thicker and more liable to burn, it is removed farther and farther from the fire.

By means of this tray alone, the juice can be so concentrated as to render it safe from decay or fermentation, and where the "sucrate of lime" process is to be used, by making the tray long enough, the juice can by these simple means be rendered ready for conversion into pure sugar by the sucrate of lime process; but where the operator wishes to reduce the juice still further, and finally into a perfectly hard and dry mass, which would not be necessary in ordinary cases, the following continuation of the machine is added :—

2nd. This continuation of the machine is called "the cylinder." It runs on an axis, is open at both ends, is twenty feet long and three feet six inches in diameter. (This size is for the large works before mentioned). In England it is made of copper, but here it would be made of sheet iron or boiler plate, and would be like a steamboat chimney laid on its flat, with a spindle through it fastened by arms to the ontside or shell. It must be made to revolve slowly (about six times in a minute) by machinery. It is also set on such a slope that the liquor will gradually work forward to the far end of it, although each end is open, so as to receive the thick juice at one end, and deliver it still further evaporated at the other, yet the ends are so turned in by a ledge projecting towards the axis, that the cylinder will hold a considerable amount of fluid. The liquor efficiently evaporated in the tray is delivered into the end of the cylinder, which is then set revolving. As it does so, it carries the stuff up on its inside skin, and as soon as it reaches the top it drops off. Through this cylinder a blast of hot air is forced with a fan. The air may be heated by an outside skin being put to the iron chimney of the steam engine, and being forced in at the top of the skin, and allowed to pass out at the bottom, is strongly heated by the waste heat of the iron chimney. This hot blast is conducted through the cylinder, and although so hot, never burns its contents, as the particles of water carry off the heat. Where hot enough, it should be continued over the tray. The outside of the cylinder is also heated by the waste heat from the tray, or by a fire made on purpose, the cylinder being set in an arch of either brickwork or sheet iron. The action of the heat outside, and of the heated air passing through the inside, evaporates the water in the syrup most completely, and the stuff is delivered from the far end of the cylinder in a state which, when it becomes cold, is almost solid. But it may be further dried, when required, by a similar process, only the stuff now called concrete is then exposed to heat and hot blast on the *outside* of a drum, and scraped off by a fixed scraper.

In Canada, for many a year to come, we shall not require anything further than the tray and cylinder. It will be seen that this work proceeds rapidly and surely without hands, and with very little attendance, and by the time the liquid has run its course from the first end of the tray to the last and of the cylinder, it is reduced from thin water to thick syrup, which is in a state fit for keeping and storing, and for the operations of the refiner. The duration of the process of a portion of the liquid passing from one end to the other of the machine is less than fifteen minutes, and during that interval no part of it is burned into molasses or sugar that will not crystallize, or as it is called by sugar manufacturers in England and on the Continent, "Fructose."

The colour of the concrete from cane juice is a pale greenish yellow, and when mixed with water becomes cane juice again, as pure as when expressed from the cane. This shows how little the process burns it.

The concrete from the beet juice will, of course, contain all the salts, potash, &c., and these must be got rid of by the sucrate of lime or other processes; but for the ordinary farmer, the juice will be reduced to a rough impure syrup, strong enough to keep, and will then be casked up and command a ready sale, or it can be purified at a leisure time.

The great difficulty in all beet root sugar works has always been the alteration of the juice by fermentation and souring. Like all juices, the beet juice contains within itself the elements of fermentation, and where it was necessary to express into vessels that would form a store of the liquid until the defecating kettles were ready, fermentation to a greater or less extent was certain to ensue.

Souring also took place at every stage and in every corner. The large beet root sugar factories on the Continent have floors made of marble, with close joints, and every angle and chink so arranged that they can be easily and thoroughly cleansed; and notwithstanding all precautions, souring in some parts, and fermentation in others, will occur, and the only cure is a temporary stoppage of the works, and every instrument and vessel which comes in contact with the juice being thoroughly limed and scrubbed with lime water. All this trouble and risk is got rid of by the tray and cylinder The work, of course, continues night and day; and if it does not, both tray and cylinder must be thoroughly cleansed, before allowing them to stand.

The foregoing is the plan as set forth in the latest English books. The American system of rockers on the tray is, no doubt, a good one; and if not used, provision ought to be made in setting up the tray for altering the level as required. This may be easily done by allowing the brick walls which confine the fire to extend up the sides of the tray, and the tray itself to be supported on iron rods crossing from wall to wall. These rods should be capable of being raised and lowered by a screw, so that the attendant may be able to meet the wants of the juice as it gets thicker in its progress along the tray to the cylinder. There are several other points in which the process might be improved, and the risk of burning lessened; but it is always safest to try known and proved plans in the first instance, and afterwards to attempt improvements gradually.

Our Roads.

BY ALAN MACDOUGALL, C. E.

I.

The study of the histories of any of the countries of the world, whether from the very earliest historical records, or those of the times of the Roman Empire, down to the daily reports of the progress of enterprise and civilization in the New World, tell us that the first thing man does when he begins to wage war on the elements of nature, and, bringing the earth under his subjection, makes it obey the great law, "Be thou fruitful!" is to make a means of communication with his fellow men, and these ordinary means of intercourse or communication are commouly termed roads.

Formerly, people were satisfied with a mere track over hills, through swamps, or by the sides of them, as best suited their convenience, so long as they were able merely to get a horse carrying a pack on its back to go along them. But as their countries increased in wealth and importance, these tracks were formed into magnificent roads, many of which are to this day living memorials of the greatness of nations that have passed away.

In many parts of the civilized portions of the Old World are there to be seen roads that are to-day marvels of engineering talent as great as our own, and may be more lasting than many New World enterprises. The patient industry of the Chinese, the ambitious and solid wealth of the Roman Empire, the bold and daring design of the great Napoleon, in taking a road across the Alps, as well as many instances that could be quoted from the history of the island home whence many of us have sprung, and others familiar, I doubt not, to many of my readers, are matters of history, and are noted, and remarked upon, by all travellers to the present day; matters they can never tire of, as no one can ever lightly esteem the works of a race that have lived in what we now-a-days term barbarity, yet were able to put up structures that have for hundreds of years battled more successfully against the great enemy Time than the designers and constructors of them were able to do. These grand and lasting memorials to the greatness of bygone ages are not lessons to be lost upon us, and although it is not intended to draw

any comparison with them for the purposes of these papers, reference may occasionally be made to some of them.

Like everything in this world, a road must have a beginning. Started from a mere bridle track or a bush road, many of the finest roads of the world have, by the labour of succeeding generations, been brought to their present state of perfection. Considering the ages in which they were made, and what we now call the want of civilization, these roads progressed slowly as the wants of the age required. Doubtless the people who lived in the "good old times" considered themselves what is now called "very fast," and thought stage coaches and macadamized roads wonderful inventions. But in these days of steam, electricity, and ocean cables, the wants of the day are far more keenly felt than many of my readers can remember to have felt them thirty years ago.

We can read with astonishment of travellers deploring, about the end of the last century, the agonies of the road from London to Birmingham—roads that were on a par with some of our back country roads, full of ruts and bad bridges; but are, and have been, probably in the memory of this generation, marvels of skill and perfection.

In the opening up of a country the first thing necessary is the way of communication, and the sooner one man is able at all times to get to his neighbour, and to do so easily, the sooner will that particular district, township or county, advance. In the prosperity of a district, every one in it is individually concerned, quite as much as in the improvement of his own personal property, therefore it is the more necessary that everybody put his shoulder to the wheel and help the roads forward.

Every district, or let us say county, is not in the same condition with regard to improvements, just as every man is not as well able to spend money as his neighbour; yet a man who cannot spend money at once on his property can, by his industry and toil, expend, over a number of years, a sum corresponding to the sum laid out by his richer neighbour. His property is thereby benefited, and he does not grudge his outlay. So with a county; it may not be able all at once to spend $10,000 on making good roads, but by every one in it doing something every year, probably in ten years it reaps the same benefits that it would, had it been able to expend the $10,000 before, and also, having no debt, is now, perhaps, in a condition to spend that sum of money.

In the countries of the Old World, there were always found men of large means and fortune, or possessed of great political power, who were able to command large sums of money for various purposes. We all know of the large tracts of land in Britain and elsewhere, owned by single individuals, which have been in their possession probably for hundreds of years. These men were able to spend a large sum of money at once; but in counties where every man has only got a small portion, and came only with the fortune of a robust constitution and strong pair of arms, as he progresses in the world so everything around him must progress. Step by step he goes on, learning as he goes the value of improvements in implements of husbandry, but too seldom learning the benefits of improved roads, or too callous, if he knows, to do anything whereby he, as well as his neighbour, is to be benefited, and the progress of his county and country promoted.

Arrangement of Farm Buildings.

Convenience and simplicity should be more studied in the arrangement of farm buildings than symmetry.

Neatness, compactness and warmth are the great points always to be kept in view by the farmer in laying out or adding to his cattle houses or barns.

"Time is money," and any arrangement which will render the work of feeding and attending on cattle easier, and to be performed in less time, should be carefully carried out, especially in Canada, where seasons are short and wages high. Besides, if men perceive a neatness and compactness in the internal fitness of the buildings, and a desire to make their work less onerous, they will generally take a pride in the superiority of their employer's arrangements over those of the neighbours, and will attend more carefully to and carry out more thoroughly the operations of winter feeding.

Such buildings as are erected should be upon the north-east and west sides of the yard, leaving the latter open to the full benefit of the morning and mid-day sun.

In Canada the bank barn is undoubtedly the most convenient, giving a great capacity in room on a comparatively small area.

Homesteads, however, vary with farms, and it would be as inconsistent to dictate the plan of the farm buildings as of the farms. There are, however, certain points or general rules which the farmer will do well to bear in mind ere he commence either building new accommodation or adding to former barns or outhouses.

Convenience and economy of space are almost synonymous terms, and these are the great points to be kept in view. Good ventilation is as essential to the well-being of stock as of man.

Cattle should be kept in a warmer stable than horses and sheep, should be sheltered from all damp, but confined in open and cool steadings.

It is a great mistake to stable working horses under a bank barn, for such stables are always very warm and usually dark. When horses thus stabled are taken out, they feel the change of temperature most keenly, and unless treated with far more caution than is usually accorded to teams upon the road, are sure to take cold. The rapid transit also from comparative darkness to the glaring light of a bright winter's day is most injurious to the eye, and very frequently produces weakness in that organ, and in many cases lays the foundation for periodical blindness or ophthalmia, too often the forerunner of total loss of the eyesight.

A thorough ventilation of all stock houses is necessary to carry off the ammonia and other noxious odours which emanate from animal dung.

To return to the main barn. Such should be built strongly and capacious, for a large barn is put up comparatively more cheaply than one in which the farmer may be pinched for room. Barns should not be battened, to allow of the grain and hay receiving as much air as possible upon all sides. No barn should be built without one or more shuttered ventilators upon the roof, to allow of the passing of a thorough draught from sill to rafter.

The position of the granary is, I think, too little thought of in Canada. The granary is usually built in under a swing beam, "cabined, cribbed, confined," very hot in the warm weather, ill ventilated, ill lighted, and with no circulation of air.

Not only are all these conditions very injurious to large bodies of grain, but much valuable space in the barn is wasted during the harvest, when we require all our barn room for the unthreshed grain, and usually have our granaries almost empty.

I should advise the grain room being built in the shape of a lean-to to the barn, or better still, as a detached building, allowing the access of air between it and the barn, if it be only in the space of a few inches.

Every granary should be thoroughly lighted, and have a ventilator in the roof. It should be divided into suitable bins, leaving a good gangway between, with sliding boards to take out in the side bordering this gangway. Each bin should be raised an inch or two above the main floor, to allow of a thorough circulation of air; and it is well worth the expense to build the bottom of our bins by laying fine wire netting upon narrow and deep joists about two inches apart, running from the gangway to the opposite wall, thus promoting a draught between each joist through the netting, and up into the heap of grain.

This will help to keep out the rats, and keep grain which may have a tendency to to heat quite cool.

These fixings will no doubt be set down by many farmers as creating "too much bother," but the saving of a very few bushels of grain will well repay both the time and money expended in their arrangement.

I went into a farmer's granary the other day, and found that he had the walls and

the floor covered with tin, to prevent, he said, the access of rats. I was almost stifled, and yet he was surprised to find a lot of barley, which he had cleaned and put away, heating and discolouring rapidly. Which would do the more harm? The rats (who, by the way, might be kept down by other means) eating and carrying away their small quantum of grain, or the heat, which will destroy in a few days hundreds of bushels?

The detached granary may easily be kept free of rats. Raise it upon cast iron stands; or, easier still, upon posts, encircled by large glazed tiles cut in two, such as your correspondent, W. H. Mills, uses to protect his fruit trees from mice. There will then be only the door from the barn to watch.

This question of providing constant access of air to grain in heaps, good ventilation, and plenty of light, is one of very great importance to the farmer, and unless he attend to and provide for these conditions, he will assuredly lose as much produce as would, if converted into cash, build him a dozen granaries.

C. E. W.

How to Obtain Ammonia.

It has been demonstrated in experiments carefully conducted over a series of years, in England, that the wheat plant, during the course of its growth between seed-time and harvest, *destroys ammonia*. That is, a larger quantity of ammonia is required to perfect a crop of wheat than the entire crop, both straw and grain, contains when matured. It was found that to ensure a successful crop of wheat required the plant consumption of five times as much ammonia as the crop grown will yield. Now, the wheat plant is dependent almost entirely for its supply of ammonia upon what it can eliminate of it from the soil in which it grows.

Further experiments showed that clover, peas, beans and turnips do not destroy ammonia during their growth, but obtain what they need from the atmosphere, and retain it in their tissues. Hence it comes that one of the chief means of supplying any deficiency of ammonia in the soil for the production of wheat is to be found in turning under green crops of clover or peas, or burying the tops of turnips, beans, &c., left on the land. On a farm, therefore, where wheat or barley is grown extensively, the soil soon becomes exhausted of ammonia, unless that is supplied by artificial means, either through the feeding of stock in order to supply manure to the soil, or the rotation of crops that, not destroying, but rather attracting ammonia from the atmosphere and retaining it, help to add it to the soil. An average acre of clover or peas contains in roots and tops about 80 pounds of ammonia, equal in value for a wheat crop to twelve dollars.

Whether this clover crop be ploughed under as a green crop, or cut and fed to animals, and afterwards returned in the shape of manure to the soil, it would result in giving precisely the same amount of ammonia. But the roots contain the largest proportion of the ammonia, and these could not be used as food for stock. Still, if we grow clover as a renovating crop, cut for two years, and feed ont the tops to stock and afterwards return the manure so made to the land, and together with it plough up, and so destroy and subject to decomposition the roots of the clover, we shall obtain a sufficient amount of ammonia in the soil to mature a heavy crop of wheat or barley. Hence it is evident that the success of the grain-grower (for barley, oats and corn require nearly as much ammonia in the same way as wheat) will be mainly dependent upon two things—either his ability to make or procure sufficient manure to make amends for the loss of the ammonia destroyed by the grain crops; or to grow alternately, crops of clover or peas, turnips, &c., in order to furnish the ammonia partly through their attraction of it from the atmosphere to the soil, or the turning them under as a renovating crop.

A farmer of Springfield, Ohio, recently picked 400 bushels of cranberries from three acres, and sold the lot for $1,520.

The estimated area in hops in England is now 65,600 acres, and is gradually increasing.

One marked difference in English and American farming is forcibly presented by a correspondent of the *Country Gentleman* in the statement that an English tenant farmer, liable to be dispossessed of his place on six months' notice, buys corn brought 3,000 miles with which to fatten animals, doing this chiefly for the sake of the manure, while an American farmer owning the land he works, will sell even his hay, and feed no animals for the purpose of enriching his own land.

TOP DRESSING ON GRASS LANDS.—We have frequently called the attention of our readers to this method of sustaining the fertility of meadows. The compost should be fine, so as to be spread evenly on the surface, and find its way readily to the ground in small particles ready to be dissolved and carried down to the hungry months below that are reaching out in every direction for food. Manure or compost applied in lumps is of very little value in enriching the soil. The surface manuring should be done early, in order to have the best effect on the crop of next season. If the manure is reduced to the proper condition of fineness, and is not already exhaling its valuable properties in the process of fermentation, there is no occasion to fear loss by evaporation. Its nutritive properties will be drawn downward to meet the requirements of the growing grass.—*Vt. Record and Farmer.*

Stock Department.

Report of Judges on Live Stock at the Royal Agricultural Show, 1870.

An official report on the exhibition of live stock and the trial of implements at the Royal English Agricultural Society's Show, held at Oxford, last July, has just been published in the second part of the Society's journal, from which we propose making a few gleanings for the information of our readers. The report is exceedingly elaborate, and abounds in matter of the highest interest to the inquiring practical agriculturist. We propose in the present paper to confine our remarks and extracts to the department of live stock.

It is noteworthy that the first exhibition of the Society was held in the classic city of Oxford, thirty years ago, when seven acres of ground more than sufficed for its requirements, whilst on the late occasion ten times that area was fully occupied with many miles of shedding. One feature of the Society's annual show is deserving of special notice and commendation: as one Sunday at least occurs during its proceedings, arrangements are made on the grounds for the reverent conducting of Divine worship. On the last occasion two services were conducted by the Bishop of Oxford and one of the Canons of the Cathedral, when at least 500 persons, consisting principally of servants and others in charge of stock, &c., formed the congregation, morning and afternoon. The preachers made themselves clearly understood by the least educated of their audience, leading us to believe that these services are as effective as they are interesting.

It would appear that the late Oxford meeting was peculiarly distinguished for the very large amount of sales that were made on the grounds, both in stock and in implements. The report speaks, in reference to the former:—"Probably at no previous exhibition have buyer and seller been brought together so frequently with success, and the prices realized for many of the animals at once bespeak their superiority, and indicate the liberal spirit of the purchasers, of whom there were some of the most enterprising present from the United States, Canada, and Australia. Shorthorns and Herefords seemed most to take their favour, and our choicest specimens in form and blood—Bates as well as Booth, and other kinds—were purchased for the above colonies. They are surely entitled to possess them, with our best wishes for their success in distant climes, for the weighty considerations left in exchange. The enormous or almost fabulous prices realized of late for Shorthorns are beyond all precedent. Two thousand guineas for a seven year old cow was offered and declined; the writer has it from the best authority. This priceless treasure is Lady Fragrant,

(Extract of Gold, or The Nugget, would have been equally appropriate names) owned by that well-known breeder, Mr. T. C. Booth, of Warlaby. Selections were made from the same herd at 1,500 and 1,000 guineas each. Duchess blood, too, now so rare, has not escaped the compass of these spirited visitors, as Mr. Cochrane, of Montreal, has charmed away two of Captain Gunter's gems, both yearling heifers—Duchess 101st and Duchess 103rd—the consideration being no less a sum than 2,500 guineas! The first and second prize yearling heifers at Oxford also found buyers at 500 guineas each. The first, an undeniably good one, owned and bred by Mr. D. McIntosh, of Havering Park, Essex, goes to Australia, and her second competitor, bred by Mr. Dudding, follows suit to America. All this, and much more that cannot be given in detail, should be highly encouraging to breeders, and in the absence of Continental buyers, the vast amount of business done is the more astonishing."

The Live Stock department of the Oxford show comprised 441 cattle, 203 horses, 550 sheep, and 192 pigs. All classes, except horses, of which there was a considerable diminution, were in excess of the Manchester meeting the year previous, at which unusual attractions in the way of hunters, hackneys, &c., were offered by liberal prizes of the local committee.

The Royal, for some cause or other, has never been very highly distinguished in the department of horses, the Yorkshire Society's show frequently excelling it both in number and quality. One of the judges writes as follows of the Clydesdales:—"We have always looked upon these animals as good on the land, and superior to most for heavy work on the road, but if the specimens brought before us are a fair sample of the breed, their reputation is not likely to be increased by this exhibition. At any rate, I must express my disappointment at finding so many inferior animals in the short entries which composed this class." If the writer had attended any of the Highland Society's shows, where the Clydesdales often form 90 per cent. of all the breeds on exhibition, he would most probably have seen enough to modify very largely his opinion. "Years ago the feet of the Suffolk horses were considered their weak place; they will now bear comparison with any other breed exhibited, and certainly the Clydesdales and 'shire-breds' at this meeting were far worse in this respect than the Suffolks. My notebook shows many marked as having indifferent fore-legs, light in substance, and with a retreating cannon-bone—a formation weak and unsightly! This appears to be a prevailing fault. Some few others had bent hind-legs and coarse hocks."

Of the Suffolk horses the report goes on to speak as follows:—"The Suffolk has long been a recognized and distinct breed, and, perhaps, with the exception of race-horses, none have been bred with more care and attention. Every distinguishing point for which the breed has long been valued has been preserved and cultivated, and the prevailing characteristics of colour, quality, and compactness of form, with activity and strength, have never been lost sight of. Distinctive feature at first sight gives the breed a great advantage in attracting the attention of a casual admirer, but has little or no weight with those accustomed to sift the merits and balance advantages in individual specimens of various breeds. Competition beyond their immediate district has brought about vast improvement in this breed. Want of action, bad feet, and bent hind legs, are no longer noticeable in the Suffolk entries, and no meeting has given better proof of this than the one just held. We hear breeders of Clydesdales, Shirebreds, and Suffolk, holding to their own with unflinching pertinacity; as agricultural horses each are subject to criticism from the best of judges at their meetings; and, unless the listener is bigoted to his favourite breed, he will quickly throw aside his prejudice and admit that no one kind of horse is suited for every locality, and he will probably begin to notice the fact that where distinct breeds have for ages been associated with certain duties or certain districts, they have not been selected for the work without a substantial reason. Of what use would the immense weight of a slow, heavy action of the Shirebred be on the soils of Suffolk? and no one would recommend the farmer, whose soil is of the stiffest clay, and who breeds for the railway, the dock, or the brewer's dray, to hire a "Harwich Emperor" for his mares, or purchase a "Bury Empress" to fill a vacant stall in his plough stable; and the very weight of the Shirebred would distance him with the quick action of the Suffolk in his own county; while the Midland counties man would talk of the tenacious toil, and ask if the Suffolk horse, hardy and active as he is, could stand the work required for such a district? The Clydesdale breeder would point to the quays and streets of Glasgow, and call for an animal better suited for the work he would there find. These are questions safer left to those whose experience should teach them what their own requirements are. As breeders our business is to eradicate unsoundness, perfect the form, and preserve the characteristics which should denote the breed we adopt; as judges we felt our duty was to point out the individual specimens which give the best evidence of the breeder's success, as tested by such a principle."

The Channel Island Cattle classes made a great and interesting display, and are said to have much exceeded in importance any recent exhibition. These beautiful and useful animals appear to be winning increased admiration every year, and they are highly prized in private dairies, yielding large supplies of milk, exceedingly rich in cream and butter. These cattle are scarcely known in Canada, but they have of late been making progress in some sections of the United States, where, as in Europe, they are much esteemed for their dairy qualities. At the Oxford show some Alderney heifers were sold for 70 guineas each, a sum indicating the high repute in which the breed is held by practical men. It appears that the Society has been in the habit of arranging the Jersey and Guernsey cattle in the same classes, whereas there are very distinctive points of difference between them. The judges respectfully submit to the Council, the advisability of making a thorough distinction for the future in the classes hitherto denominated "Channel Islands Cattle," inasmuch as the Jersey and the Guernsey breeds, for which the classes are intended, are entirely distinct, and have not the slightest degree of affinity.

The sheep department was of a very high order; the display a wondrous one with few exceptions; the various classes have never been equalled in number or quality. The local or "Shire" breeders certainly surpassed themselves, and did battle in tremendous force on their native soil. The fine old standard breed of Leicesters, going back to the days of Bakewell, is always pleasant to look on. Leicesters unmistakably show pure breeding and high quality, in a degree to make their "landmark," whereby to correct the deformities resulting from injudicious crossing in other directions. Indeed, the owners of pure-bred flocks, of whatever kind, should, in this respect, be regarded as public benefactors, without whose care and help all would become chaos and confusion.

The Report goes on to state that "The Downs" one and all presented a most imposing sight, for in *them* lay the strength of the sheep department. It was not without reason that the efforts of the Oxford Down breeders should be looked to here, on their own ground, with special interest; nor can any impartial critic deny the meed of praise due to them for such a display, both as regards numbers and quality. Next in order came the beautiful Southdowns, the perfect type in form and character, at once arresting the attention of every lover of beauty. Throughout this high-bred class could be observed a uniformity so much wanting in the kindred classes of Oxford Downs, the breeders of which may well take example here for their edification.

The Shropshire Downs have been steadily rising in public estimation of late years; they are not wholly unknown in Canada. The subjoined remarks will not be without interest on this side of the Atlantic:—"This very useful class of sheep is gaining in popularity, and it is not surprising that is so, for in outline they dimly resemble the more aristocratic Southdown. They are hardy, sound, and prolific, and appear to flourish in all districts where they have been introduced. Numerically they were superior to any class exhibited, and this position they

have held for some years at the Society's shows. Their value will, however, be much enhanced in public estimation when their breeders shall have accomplished the removal of that stain which has been so frequently and so forcibly pointed out of late years, viz., the want of uniformity in type and character; for black, light and speckled faces and legs are seen side by side, with close and open fleeces; thus marring their otherwise good appearance. This should not be, and if their breeders, as a class, desire to hold, as they may do, a foremost position, a "local parliament" of the most intelligent breeders should be called, to determine among themselves some standard or true type to aim at, and once agreed, let no other be recognized; then, and not until then, will the Shropshire Down hold its proper place as a distinctive and high-bred sheep." The report concludes by suggesting to the breeders of Shropshire sheep the extreme importance of endeavouring to establish more uniformity of character, by aiming each at the production of animals possessing the *same qualities*, which all should endeavour to perpetuate, viz:—

1st.—That a Shropshire sheep should possess great depth of firm flesh, indicated by a good muscular neck, straight and wide back, with ribs well sprung, and a heavy leg of mutton.

2nd.—That the face and legs should be of a uniformly dark colour and well covered head; the fleece thick set and free from grey.

Winter Feeding of Farm Stock.

There are two principles involved in the matter of feeding stock in winter. One of them is that sufficient carbon should be supplied to keep up the animal heat of their bodies. Those substances which supply this carbon are principally vegetable, and are known to chemists as carbonaceous compounds. Among them are starch, sugar, and gum, which compose the chief part of the grasses, roots, and some kinds of grain, in conjunction with the elements of water to a greater or less extent.

If we take carbon, which is only a scientific name for vegetable charcoal, and burn it in a stove, it gives out an amount of heat proportionate to the quantity burned. Now, on a cold day, as is well known, more fuel is required to keep the stove at a given heat than on a warm day, and in proportion as the cold is greater so is the consumption of fuel to radiate out such an amount of heat as will counteract the effects of that cold on the animal system. The carbon contained in the food consumed by animals is burned in their bodies in a manner analogous to the burning of fuel in a stove, and gives out heat in the same proportion.

The temperature required in the bodies of all warm-blooded animals is the same at the equator as at the pole, namely, 98 degrees, that being the normal condition of heat required to keep their circulatory system of blood in a healthy state.

Now, as we cannot well supply artificial heat to their bodies from without, we must keep them supplied with sufficient carbon to generate heat by decomposition within their bodies. This can only be done through the food they consume, and the colder the external air, the more food they will require in order to produce sufficient heat within. This heat is generated through the agency of the process of respiration. Hence they require more food of a carbonaceous character, and will consume more of it during cold weather than in warm.

To keep up the animal system, therefore, in a healthy and thrifty state, they require sufficient carbonaceous food to maintain the animal heat of their bodies to a certain degree of temperature, namely, blood heat.

Now, if the animal system is well nourished, healthy, and full of muscles and flesh, whatever carbonaceous food is consumed beyond the requirements of the animal to maintain the heat of its body, will be stored up in the system in the form of fat.

But the system requires somewhat more than carbon to keep up its functions of vitality. It also requires nitrogen, which is an organized substance in vegetables, analogous to flesh and muscle in animals. It is believed by many chemists that vegetable nitrogen is converted into flesh in the animals without first undergoing the process of decomposition. From this it has been maintained that the nutritive or flesh-forming quality of the food consumed by animals is in direct proportion to the amount of nitrogen it contains. The leguminous tribes of plants are rich in nitrogen. Clover contains more flesh-forming elements than any of the grasses proper. Peas contain three times as much nitrogen, in proportion to their amount of carbon, as Indian corn. Bran contains more of it than fine wheat flour. Hence it comes that in feeding young animals, or those in poor condition, when we desire all excess of food to go towards forming flesh and muscle, and add to the size and weight of the animal before it attains maturity, we must give a due proportion of nitrogenous food along with the carbonaceous, otherwise any excess consumed beyond what is required to maintain the animal heat of their bodies will go towards laying on fat, without there being a fair proportion of muscle to form the lean.

But in animals already full fleshed, arrived at maturity, and therefore in high condition for feeding for the butcher, we must endeavour to lay on fat by feeding an excess of carbonaceous food, of which corn probably contains the largest amount in proportion of any grain we grow.

When we put up young pigs to fatten they need peas in order to supply substance for their growing muscles; but if we put up a full-fleshed grown hog to fatten we shall find most profit in feeding Indian corn. So if we want our horses or oxen to be able to do hard work, we must give them such a proportion of nitrogenous food as will enable them to replace the constant wear and tear of their muscles, but if we want to feed them up for show or sale we can give them softness of feel and a glossy coat by feeding Indian corn.

In order to enable farmers to make their calculations as to the proportionate value of some of the leading crops they grow, as regards the feeding of stock, we give a table showing the relative proportion of carbon and nitrogen in such as we can find chemical analyses of, premising that they are not to be looked upon as more than an approximation, as different authors give varying results as regards their analyses:—

PROPORTION OF CARBON TO NITROGEN.

	CARBON.	NITROGEN
Wheat	59	10 to 15
Barley	69	6
Oats	80	13
Rye.....	69	16
Indian Corn ..	84	15
Buckwheat	50	14
Peas	40	23
Beans	44	23
Corn Fodder ..	50	5
Meadow Hay..	40	7½
Clover Hay....	40	9½
Pea Straw.....	45	12
Wheat Straw..	35	2
Wheat Bran....	69	16
Potatoes	12	½
Turnips.....	10	1
Carrots	10	2

Where there is a large proportion of starch in the food, as, for instance, in potatoes or Indian Corn, there is a great advantage in cooking the food before feeding, for the reason that the heat of the stomach is insufficient to burst the feculent grain of which starch is composed, and unless that is done, much of it passes through the animal in an undigested state.

Black Noses in Shorthorns—Are they a Proof of Impurity of Blood?

SIR,—As short-horned cattle are yearly becoming more and more popular with the farmers of Canada, and the remark is occasionally made that "no pure Shorthorn should have a black nose," I copy an extract from the Shorthorn correspondent of the English *Farmers' Magazine*, remarking ere I do so, that 2nd Lord Oxford, exported to England by Mr. Sheldon, had a very dark nose; also that one of the Duchess cows, bought at Earl Ducie's sale for a very high figure—Duchess 64th, I believe—had a spotted nose; and it is in discussing this question that the correspondent says: "The black nose upon a pedigree Shorthorn is a blemish at present in the eyes of the breeding world. That it should be so thanks to the Yankee, who objected of old to any but

the 'raw nose,' else what harm could that be which is simply a relic of ancestral inheritance from the celebrated Galloway heifer and Chillingham herd, which were used so freely in Cunningham's alloy, and which is continually reappearing in the oldest and best strains—some great Royal prize-takers—of the pedigree stock, as every reader knows? Names I will not give, as I have no wish to depreciate any gentleman's herd. I will only remark that Belvedere had the defect latent in his composition, and that the Chilton cows abounded with it. The oldest breeders in private converse make no secret of this objectionable nasal tint, cropping up occasionally under most unlikely circumstances. From a scientific knowledge of the dip of strata, Sir R. Murchison, amidst the Ural Mountains, predicted the finding of the Australian gold fields. By an analogous acquaintance with the elements that underlie the famous Thorndale bulls, it was long ago predicted by a celebrated living Shorthorn authority, that an occasional black nose must crop out in that stock. I was not myself at the Havering Park sale, but have certainly been repeatedly told by competent authorities that Baron Oxford had undoubtedly a smutty nose. Mr. Eastwood did well to have an inquest in the matter, and we will devoutly hope that the shadowy dim spot which is allowed to disfigure the luminary may not spread nor reappear in his progeny. But as America started the fuss by objecting to black noses, let it now make the *amende honorable* and confess itself hypercritical in the first instance. The emancipation of the blacks has been of late their praiseworthy mission As regards Mr. Eastwood's herd, be they all tainted in this terrible manner, still they would fetch by auction, I do not hesitate to say, the highest average that has ever been obtained. The gentleman who founded the first Townley herd, and who never meddles with stock of any sort without gilding it, will not suffer from what really is only a vulgar prejudice. I do not mean to say that it would not be better if we could eliminate the dark stain from our herds; but seeing how deeply it impregnates them, I do not hesitate to state that I, for one, should not decline to breed from an animal of excellent points and fine quality, even though he may appear to have carried printers' ink in his scent-bottle. But to settle the matter more immediately and thoroughly—Messrs. Eastwood and Culshaw, are they not in the Shorthorn world of authority to set fashion even equal to that of the Empress Eugenie? 'Let there be golden hair,' and there was golden hair. The Empress had only to ordain and the thing was done. Let our leaders be as resolute, and declare that, at least, the quadroon tint shall not condemn a bovine beauty. And as we are upon the subject, let them issue an edict further that the *white* colour shall be equally costly with the red and roan, for have they not proved in the course of their victories that the white heifer is usually pre-eminent in loveliness of shape, in grace, in wealthiest quality? Again, are not the very richest roans often the offspring of a white cow? Such, at least, has been my own experience. To say that the white are more delicate, is simply not fact, as any one who likes may prove for himself, and as the most experienced breeders and feeders readily allow. To depreciate the cream hue only serves the purpose of a few far-sighted buyers. That Mr. Eastwood is superior to this prejudice is proved by his using that grand white bull, the Hero."

Such, Mr. Editor, is the opinion of a celebrated English Shorthorn authority, and I quote it for the consolation of any of our breeders who may have had a dark nose "crop out" among his thoroughbreds. And I had recently a conversation upon this subject with the manager of one of the largest Shorthorn herds on this contieent, who had lately returned from England. He said that it was not considered of such importance there as it is here, though it was, of course, a blemish, but not any evidence of impurity of blood. EMANCIPATION.

December, 1870.

Wintering Calves.

It is a common belief among herdsmen that it is as much a task to carry a calf through the first winter as it is the second. It has been a fancy of ours to handle calves for three-score years. About the first hard work we tried to do was to yoke up the calves and teach them to go at the word of command. In our boyhood it was the practice to feed them nubbins of corn or a few oats besides their hay, and when we began on our own hook we fed carrots, apples, turnips and potatoes. Forty years' experience has convinced us that there is little trouble in getting through the first winter, if the calf is in fair condition to begin with. We prefer one or all the articles above named to grain.

Calves should have a place by themselves, where they can enjoy their food undisturbed by older animals. A good shed is indispensable; good early cut hay, and free access to good water, are equally important. Straw or leaves for bedding should not be overlooked. Now if you will visit them once or twice a day, always with regularity, with a quart apiece if twice a day, of finely chopped carrots, you will be pretty sure to find them glad to see you, and ready for their rations. We give the carrot preference because experience has shown us that for a calf it has no equal. Regularity is more important with a calf than older animals, though it pays on all. With these provisions, we have scarcely failed in keeping our number as good in the spring as in the fall. We have used a stable, but prefer a good yard and shed with a place where they cannot get on the food with their feet.

Teeth as a Test of Age.

To the Editor.

SIR,—I noticed in your answer to a "subscriber," respecting teeth as a test of age, that while regarding the teeth as amongst the surest marks of the age of any animal, still you admit that high-kept and rapidly-growing sheep may acquire their second teeth much earlier, and according to one authority, by several months or a year.

The usual order in which the temporary incisor teeth are succeeded by the permanent is as follows: When the animal is about twelve months old, the two centre teeth are replaced by two broad ones. The following year, the next two lateral teeth are succeeded by two others, giving the animal, when two years old, four broad teeth side by side; in the third year six, and the fourth eight, when the change is completed.

I carried the "crook and plaid" for many years in the old country, and was in charge of many sheep which were specially fed for the English market; and where those of a certain age were sold in lots, the teeth were the only guide taken to indicate the age, and no instance ever came before me where a year-old animal showed four broad teeth, or a two-year old six; and my experience of sheep in this country is the same, and in fact I never heard of any instance in which sheep, however well-fed or of any breed, which had the teeth usually found in those a year older, till within the past few years, and those were in animals exhibited at agricultural shows, and first at the Provincial exhibition.

In fact, I have noticed when there is a variation from that usually seen, even in the best fed animals, that the permanent teeth in coming are more apt to be quite a time later in making their appearance, but never before, so that when four broad teeth are seen, I am positive that the animal is two years old, and may be several months more, but never less than the two years.

I would not trouble you by writing this, concerning the particular importance I lay on the teeth as the only indication we have of the age of the animal, were it not for the imposition we yearly find at our annual shows, both provincial and local, where animals of a certain age are classed with those of a younger; besides, many farmers wishing to improve their stock are taken in by unscrupulous sellers, even among the *respectable* stock-breeders of Ontario, in substituting two-year olds for yearlings and three-year olds for two year olds, and when challenged by those who have regarded the appearance of the teeth as a mark to denote the age, fall back on the doctrine you wish to inculcate, that high-fed animals *may* cut their second teeth a year before that which occurs in the majority of animals—a doctrine which, in my opinion, must be received with caution.

In order that you may have some idea of the number of such precocious articles which appear at our Provincial Exhibitions, I will give you the following, which came under my own observation, in this section of the country, and I might add to the number. Besides, the fraud was increased by the animals carrying nearly two years' wool on their backs, or at least the past year's and the present summer's, from defective shearing.

In a neighbouring township a farmer bought a ram from a respectable Ontario breeder, for which he paid $80, with four broad teeth, which was entered both at Montreal and Kingston as a yearling, taking first prizes in both cities. On his attention being drawn to the teeth, he wrote to the seller, who fell back on the high-keeping as the cause; but at the same time sending him, I presume as a *solatium*, two splendid yearling ewes.

This occurred a few years ago, but this fall, a gentleman belonging to this township purchared at the Exhibition in Montreal a ram, which took a first prize, and was guaranteed to be but two years old, which has six broad teeth.

In some of our township shows, sheep to which prizes had been awarded at Provincial Exhibitions have been prevented from competing by being but partly sheared the preceding spring. The old wool adheres together more than the new, is of a darker colour, and by being combed stands out, giving the animal the appearance of having a greater quantity of wool than it really has.

M. McGREGOR.

Roxborough, Nov. 23, 1870.

NOTE BY EDITOR.—While we can give no other answer than that already published to the question of the reliability of the teeth as a test of age—namely, that this index is the best, but not absolute and without exception—we are glad that our correspondent should call attention to the frequent frauds attempted on the score of the exceptional possibility. That these deviations, however rare, do occur, is attested by the most eminent authorities. Facts of the kind have come under our own observation, and we know from analogous instances in the human subject, as well as among the lower animals, that precocity and abnormal development of the teeth occasionally present themselves. The subject has frequently given rise to dispute, and at one of the recent shows of the Royal Society good evidence was adduced to prove that certain animals which the judges had disqualified from this teeth test, as having been wrongly entered, were really of the age represented, and younger than the teeth indicated. We believe, however, that these irregular cases arise rather from natural precocity than high keep, and are quite sure that authentic instances of the kind are so rare that anything like a frequent representation of such precocity on the part of exhibitors or flockmasters should be received with the gravest suspicion.

Acorns Poisonous to Cattle.

A disease which the London *Field* believes to be caused by the animals eating acorns, has broken out among cattle in England. In 1868, many cattle died in England of a disease, the immediate cause of which was the consumption of acorns. Young cattle were the principal victims, but the older animals did not escape.

In some of the animals which were examined after death, in the autumn of 1868, the roof of the mouth was found to be extensively excoriated; the papillæ in the first stomach (rumen,) were blanched on their apices, and cracked, as if they had been exposed to the action of some powerful corrosive; the leaves of the third stomach (omasum) were commonly much congested, and in many cases hard masses of partly digested acorns were found between them.

The present outbreak of the "acorn disease" happens under precisely similar conditions to those which obtained in 1868—a long drouth, scanty crops of grass, and an abundant supply of acorns, which have been plentifully scattered over the pastures by prevalent gales. In 1868, the first cases of disease were detected at the end of September; this year the affection appeared a fortnight later, but in each instance as soon as sufficient acorns had been blown to cover the lands on which the cattle were feeding.

A Model Stable Keeper.

An exchange in giving an account of one of the best Livery stables in New York, says the proprietor of the establishment is extremely particular as to the men he employs, and the following are among his rules:—

"First—No man will be employed who drinks intoxicating liquor. His men, like his horses, must drink water—cold water only.

"Second—No man must speak *loud* to any of the horses, or in the stable where they are. Horses of good blood are nervous; and loud, excited conversation is felt by every horse in the stable, who hears it. Excited words addressed to one horse are felt by every other horse who hears them, and keeps them all nervous and uneasy.

"Third—No man may use profane language in the hearing of the horses. They are gentleman's horses, and understand what profane language and the excited tones which accompany it mean."

The last is no doubt an excellent regulation, though the reason assigned is somewhat ambiguous, and rather hard on the "gentlemen."

It is best to handle calves and colts as much as possible, and pet them, lead them with a halter, and caress them in various ways. Young stock managed in this way will always be docile and suffer themselves to be approached and handled, both in the pastures and in the barn.

Veterinary Department.

Tetanus in Horses.

Some time ago, in a former number, we alluded to this alarming and terrible affection, and we have been induced to do so again, as we have had several cases lately in our own practice, and have also been informed of its occurrence in various parts of the country.

Tetanus is a nervous disease, producing a permanent contracted condition of the whole or part of the voluntary muscles. The name usually applied to this disease is "lockjaw," from the circumstance of the muscle which opens and closes the jaw being rigidly contracted. The proper designation of such cases is *Trismus*, signifying that the muscles of the head and neck are principally affected. When the muscles that raise the head and neck are violently affected, producing a crouching of the back, with the head carried stiffly erect, the term *opisthotonos* is applied.

This disease is usually described as of two kinds—*traumatic* and *idiopathic*. Under the former term are included those cases which supervene upon some visible injury, as pricks or punctures to the foot, injuries to any of the joints, or in fact any part of the body. By idiopathic is understood that kind occurring where no visible lesion can be noticed, and possibly resulting from some disordered condition of the digestive organs.

Tetanus occasionally occurs as a result of castration, in instances where the horse has been exposed to cold. It is recorded by a French veterinarian that twenty-four horses were castrated on the same day and by the same method, and afterwards the animals were four times a day bathed in water derived from a very cold spring, and as a consequence, sixteen out of the twenty-four died from tetanus between the tenth and fourteenth day after the operation.

The symptoms of tetanus vary according to the intensity of the attack. One of the earliest symtoms is a peculiar anxious expression of countenance, with a general nervousness and tendency to excitement, causing the horse to tremble slightly, and giving rise to jerking of the tail; and the *membrana nictitans*, or haw of the eye, is ejected quickly over the eyeball, and will remain, partially covering the eyeball, as long as the excitement is kept up. This action of the *membrana nictitans* is produced from the increased contraction of the retractor muscle. (By empirics this prominent symptom of tetanus is often mistaken for a local affection, and the unoffending body is barbarously removed.)

There is difficulty in swallowing, and the head is carried stiffly; the muscles of the neck and head are unnaturally prominent, and hard and tense; the jaws are partially closed, and when in this condition, the tongue is frequently injured in the animal's efforts to swallow. These symptoms increase, and the whole muscular system becomes involved. The patient stands with outstretched limbs and anxious look, and the least excitement produces a paroxysm frightful to behold. The respiratory organs are affected from the impaired action of the muscles of respiration, and a common cause of death is congestion of the lungs resulting from that condition. The pulse is but little affected, except after a paroxysm; the jaws become completely closed; the skin in many instances becomes covered with perspiration; there is frequently great thirst; and the alarming symptoms are greatly increased by the ineffectual attempts at deglutition. The animal becomes gradually exhausted, and death may take place in from four to twelve days.

Treatment of Tetanus.

Tetanus is a very fatal disease, and many are the remedies that have been tried without alleviating the painful and distressing symptoms. We only intend to allude to the general course of treatment which should be adopted, without referring to the use of many powerful drugs, which should only be used when their action can be closely watched by professional men.

The patient should be placed in a roomy box, and kept as quiet as possible, the farther from any noise the better. He should be approached carefully and quietly, as the least noise or irritation has an injurious effect. In traumatic cases, the wound or injured parts should be diligently fomented with warm water, or poultices applied when it can be conveniently done. A full dose of purgative medicine may also be given, as eight or nine drachms of Barbadoes aloes.

The extract of belladonna, in doses of one drachm three times a day, appears to be useful in this disease. The horse must be allowed plenty of sloppy food, and if the jaws become completely closed, the strength may be supported by nutrient enemata. Blisters are occasionally applied along the spine, but we consider that they are attended with bad results, and therefore cannot recommend their use.

Mange in Cattle.

The cause of mange is the presence of a minute insect (or *acarus*,) which has its habitation in the skin, and burrows its way from the surface underneath the cuticle. Mange in the horse and ox, and scab in the sheep, are one and the same affection, although the *acarus* in each differs somewhat in form and size—each animal having its own peculiar insect, which cannot be transferred to the skin of a different species.

The symptoms of mange are a constant rubbing and itchiness of the animal, which, when examined, will be found to have the skin denuded of hair in places, and having a sort of dry scurf. When this is removed by the finger, we find small raw-looking pimples, discharging a yellowish serous fluid. On examining the scab under a microscope, the *acari* may be distinctly seen. In long continued and chronic cases, the skin becomes thickened and thrown into wrinkles and folds. The parts more especially affected are the skin about the neck, breast, and thighs, where it hangs loose and in folds.

In the treatment of mange we have to accomplish two things—destroy the insect and ova, and restore the healthy action of the skin. For the former purpose almost all the various poisonous compounds of the *Pharmacopœa* have been recommended and employed, and often to the destruction of the animal. Arsenical compounds, although destructive to the *acari*, are too often destructive to the animal too, and should never be used. Mercurial compounds are equally effective, but should be used with extreme caution, as ptyalism (or salivation) will often ensue; when these compounds are used, especial care should be taken to keep the animal from cold and wet. The following form will be found efficacious:

Soft soap, one pound; Mercurial ointment, four ounces. Well incorporate, rub into the affected places, and let it remain for a day or two, when it should be removed by means of warm water and a brush. Oils of all descriptions, especially animal oils, are destructive to insect life, and having the recommendation of being safe, they may be used in all cases when the disease has not got too firm a hold on the system. Sulphur is also a very valuable medicine in the treatment of skin diseases, and like the former has the recommendation of safety. It may be used in the form of an ointment, but as greasy applications are objectionable, probably the best form of employing sulphur is that of the sulphuret of potassium, or liver of sulphur, dissolved in water. Take liver of sulphur, one ounce; water, eight ounces, to form a lotion to be applied twice a day.

In old-standing and chronic cases, the skin will require more *stimulating* treatment than any of the forms recommended above, and for this purpose the following liniment may be applied: Oil of tar; oil of turpentine; linseed oil—equal parts. Rub well into the skin with a brush every other day. It must be borne in mind, in making choice of a remedy, that no one agent can be deemed a *specific*, and that, to insure success, a change is often requisite, as after a certain number of applications even the most potent remedy will appear to lose its effect. In all cases, however, constant cleanliness is requisite, and the skin should be well washed with soft soap and water after each dressing. A mild laxative may now and then be given, and small doses of flowers of sulphur as an alterative.—*Prairie Farmer.*

Tumour after Abscess.

George McCallum, Tiverton, writes:—"I wish to know how to remove a lump on a valuable colt. The swelling is above the knee joint on the outside of the fore leg. Two months ago the colt was troubled with the flies, and swelled up about the part now affected. The swelling was considerable, but on applying remedies, was reduced. A fluid discharge continued from the part for some weeks, but at length ceased. The opening closed up, leaving a lump as already stated." Enlargements on horses' legs, situated as referred to, are frequently very difficult to remove. When they are of a callous or hardened nature, it is necessary to apply repeated blisters. In the above case, we recommend that the hair be removed from the skin over the enlargement, and an application of biniodido of mercury be used in the proportion or one drachm of the biniodido to an ounce of lard. Apply about two drachms of this ointment every sixth day, rubbing it well in.

Loss of Power in the Hind-quarters.

Paralysis either partial or complete may be produced from chronic disease of the spinal cord, or from direct injury to it, as in cases of fracture of the vertebral column. It also frequently occurs in animals in a plethoric condition, and suddenly put to rapid exercise, which is a frequent cause amongst Canadian horses. In this complaint the parts primarily affected are the coverings of the cord in the region of the loins, the kidneys, and the muscles in relation with these organs, and also the muscles clothing the loins. They become hard and tense, and the parts mentioned are in a congestive state, which, if not speedily relieved, soon terminates in acute inflammatory action.

The predisposing cause is a plethoric state of the system, induced by high feeding, without regular or sufficient exercise. In the winter season farmers' horses frequently stand in their stables for days, are largely fed, and as a consequence, the vascular organs become overloaded, and more susceptible of disease when exposed to any exciting cause, as rapid exercise and exposure.

The symptoms of this alarming affection are very quickly developed. The horse will commence his journey in apparently good health and spirits. After going perhaps for two or three miles, he begins to falter in his pace, and may exhibit lameness in one or other hind leg. He will break into a profuse sweat, which will roll off his body in streams. The stiffness of his loins increases, the breathing is greatly disturbed, causing him to heave at the flanks; the nostrils are distended and the mucous membranes reddened; the pulse is weak, and very indistinctly felt at the jaw; the ears are cold, and when the poor sufferer is forced to move, it occasions him the most excruciating pain,

which he evinces by his moans and woful looks towards the affected region. The muscles of the quarters are swollen, hard, and tense, and in severe cases these symptoms increase until the horse falls and is unable to rise.

When the congestive stage passes over and inflammation is established in the parts, the pain increases, and the pulse, instead of being weak, is full and bounding. The bowels are usually costive, and the urine is very dark; the mouth becomes hot and sticky; the redness of the eyes and lining membranes of the nostrils increase. The animal knocks his head violently on the ground and frequently makes inoffectual attempts to rise. He will raise his fore parts, but the hind are completely powerless.

Shoeing.

If the shoe does not sit perfectly level all around, and if it extends so far outside the hoof that the nails are prevented from entering the crust in the exact spot, and in the very direction, which they should, there will be a constant straining on the nails, which is injurious to the foot, and will be liable to chip pieces off the hoof. The shoe ought to be made wide across the foot at the point where the two front nails are situated. The greatest mistake frequently lies here. In place of turning the shoe, at the toe, very carefully on the horn of the anvil, the smith generally sets it up on its side and then strikes it with the hammer. The consequence is it yields at the centre of the arch, and instead of being nicely and regularly rounded in front, whilst the breadth from side to side is preserved, the nail holes on each side are brought nearer to the centre of the shoe than they ought to be. As a necessary result, the shoe at the front nail holes is too narrow for the hoof, and when it is nailed on, the crust presses on injuriously the internal sensible parts of the foot. It is difficult to convince the smiths of the possibility of laming a horse, by having the shoe too narrow in front. They generally think that the whole difficulty lies about the heel.

In putting on the shoe the nails should be driven with a gentle hand, and they ought not by any means to be clenched very tight. Hard driving and tight clenching will bend the hoof at the place where the clenches are turned inwards and downwards towards the shoe in such a manner as to injure the tender parts contained within the cavity of the foot. Besides, it is not necessary for a man to forget that he is working with the foot of a living animal. The shoe will remain on a sufficient length of time with gentle driving and clenching, provided it is properly fitted to the foot. If it have a thoroughly even bearing, there will be little stress on the nails. The nails are often made so coarse that they split the hoof, and thus keep it constantly broken. A fine nail will answer all the purposes required if it be made of the right sort of material.

We know of no worse fashion in connection with the application of the shoe, than the one which the smith has, of hammering the shoe on the one side or the other after three or four nails have been driven, for the purpose of putting it straight on the foot. This is a speedy method of making up for his total want of accuracy in placing it at first, but it should never be suffered to be practised. It strains all the nails which have already been driven, and is thus calculated to do serious damage to the foot.

Shoeing has been regarded by some as a necessary evil; still we are certain it is an evil in the horse or man only when it is improperly performed. We are confident that in both cases it would be advantageous, rather than the reverse, if the artizan could always be made acquainted with the theory of his profession, and had hands, or rather a head, for its due performing.—*Prairie Farmer.*

Cramp.

To the Editor.

SIR,—I have a colt about eighteen months old, who was taken about a week ago with cramp in his right hind leg. It was so severe that he could not move it forward or backward enough to walk for some time. I rubbed his leg well, and he recovered so that he could step as well as usual; but when he stopped walking, on starting again his leg would cramp stiff and straighten out for a moment, and then it seemed relieved, and he could walk again. After about a quarter of an hour he could walk, but was still somewhat stiff. The cramp left for that day and the next, but the third day the other hind leg was attacked in the same way, and sometimes he would step as if he had the stringhalt for one or two steps. He has been out to pasture since spring, day and night, until within about ten days, since which he has been in the stables at night and out through the day.

Can this cramp be cured, and what is the best course to pursue? R. H. S.

Fonthill P.O.

ANS.—Cramp, or spasm of the muscles of the limbs in the horse, is not often met with, and may possibly be produced from a derangement of the digestive organs. In your case, we recommend the colt to be kept in a comfortable loose box, and given a couple of quarts of boiled oats three times a day, and the limb, whenever attacked, should be well rubbed with about one ounce of the tincture of camphor. The peculiar action referred to is occasionally produced from a partial dislocation of the patella, through a weakness of the ligaments.

The Horse's Foot.

The majority of people are fond of a very large foot, but we are certain that it is a great mistake. Leaving the diseases to which it is exposed out of the question, we look upon it as an indication that all the bones of the animal are soft and porous. A moderate sized, neatly proportioned foot is just as good a sign in the horse as in the man. If we were choosing a man for walking, running, leaping or wrestling, we would never think of selecting a fellow with clock-clicking platters of feet. He would no sooner make his appearance than he would be rejected as totally unfit for the work. Why, then, should we prefer a similar development in the horse? Does he not require a wear-and-tear sort of foot as much as the man? He surely does; and one, too, that he can lift and lay in a lighter manner than if it were a fifty-six pound weight he had attached to his leg. The horse is not intended for passing over a moving sand or a quagmire, and therefore he does not require an enormous foot. In this instance, as in many others, the medium size is far the best. In fact, it is the only safe one. A foot which is either very large or very small, is liable to a variety of diseases, which will be sure to impair its usefulness. The one extreme is nearly as bad as the other. The bones of the foot should bear a reasonable proportion in size to the bones of the leg: and the hoof should be just so large and so strong as to afford perfect accommodation and protection to all the bones, ligaments, vessels and nerves which are contained within its walls. Any deviation from these proportions must be looked upon as a radical defect.—*Prairie Farmer.*

ONTARIO VETERINARY COLLEGE.—The fall term of this valuable institution has just been brought to a close. Four of the senior students passed a most creditable final examination and obtained their diplomas. The test of proficiency was very thorough, and the successful candidates won the highest compliments from the examiners for the satisfactory manner in which they acquitted themselves. The names of the passed students are A. Harthill, jun., of Toronto; —— Mayhew, and Charles Elliott, of Sandhill; and John Boyce, Mount Pleasant. Mr. John Elliott, of Sandhill, passed his primary examination on the same occasion. The examinations were conducted by Drs. Thorburn and Rowell, of Toronto; Messrs. E. T. Haggyard, V.S., Campbell's Cross; —— Wilson, V.S., London; and —— Cowan, V.S., Galt.

NASAL GLEET IN SHEEP.—In reply to a "Carder subscriber," we would say that the discharge from the nose is probably due to chronic inflammation of the cavities of the head communicating with the nostrils and nasal chamber, resulting from catarrh or cold in the head. We advise that the sheep be well fed, and the nostrils cleansed once a day with tepid water, taking care to thoroughly dry the parts; and give one scruple of the iodide of potassium in two ounces of water, morning and night, to be continued for eight days. Occasionally, parasites infest the nasal chambers, producing an irritation, followed by a discharge of matter from the nostrils.

The Dairy.

Dairying in California.

Having travelled over the dairy districts of Great Britain, France and Switzerland; with an intimate acquaintance of the dairy lands of the Eastern and Middle States, of the Canadas and several of the Western States, we found, upon the Pacific slope, conditions different from anything seen before. The climate, the soil, and the grasses are different, and, indeed, as compared with other dairy sections, so unlike, that we found it often difficult to draw satisfactory conclusions.

Up to the present time, stock has been kept upon extensive ranges. The soil is wonderfully productive in cultivated crops, but whether any of our artificial grasses can be introduced to take the place of those natural to the soil; whether, indeed, the bunch grass, under close cropping and long continued dairying, will prove enduring, are questions not satisfactorily solved.

While the climate of the coast range is low and uniform in temperature, some of the valleys further in the interior are intensely hot in summer. In the Sacramento Valley the heat is sweltering, and of course, dairying in such portions of the State could not profitably be carried on. The absence of meadows and the sowing of oats or barley for hay is a feature that at first would not strike an Eastern dairyman favourably. Yet when it is taken into account that stock run out all winter in the fields, and comparatively little fodder is required, meadows, it would seem, are of little account and can well be dispensed with. Looking over the country, as we did, at its worst season, when everything is dry and parched, one would not be likely to be misled with impressions too favourable. And yet, from what we saw and heard, we were favourably impressed with Californian dairy lands. We found stock universally in fine, thrifty condition.

It was plainly evident that much less labour was required in the care and feeding of stock here than at the East; that under ordinary management there must be a much less percentage of loss in stock from disease and accident, on account of the more favourable climate; that fancy goods could be easily made, and that with proper skill in manufacture, poor stuff ought to be the exception rather than the rule; that with the same prices for dairy products as at the East, large profits could be realized, because dairies could be managed at less expense, to say nothing of the difference in the price of lands. These, with other advantages, could not be ignored. And in saying this, we do not wish it to be inferred that we advise Eastern people with good farms, eligibly located, and who are doing well, to pull up stakes and go to California, for we believe something in the old adage, to "let well enough alone." Still, to young men seeking homes at the West, who are active and energetic, and have skill in dairy management, California, in our opinion, offers inducements which cannot be readily found elsewhere.—*X. A. Willard, in Rural New Yorker.*

The American Dairymen's Association.

The Sixth Annual Convention of the American Dairymen's Association was to be held in Utica, N. Y., on Tuesday, Wednesday and Thursday, Jan. 10th, 11th & 12th, 1871.

The full programme for this meeting was not settled on, but the following would, we were informed, constitute the main features of the Convention:

Addresses to be delivered by

Donald G. Mitchell, Editor of *Hearth and Home*, on the question: "How far and in what way the practical farmer or dairyman can best avail himself of the teachings of Science."

Professor George C. Caldwell, of Cornell University, on: "The manufacture of cheese in Germany, France, Switzerland, &c."

Joseph Harris, of the *American Agriculturist*, on: "Fattening cows on Dairy Farms."

The following topics would also come before the Convention,

Is there a gradual decline in the amount of dairy products in all our oldest dairy regions? If so, what is the cause and what the remedy? The subject to be introduced by X. A. Willard, A. M.

Is there any way by which patrons of butter and cheese factories can receive credit for the milk delivered according to its actual value, and not according to its weight or measure?

Should not every dairyman practice soiling his cows in connection with pasturage, and what crop or crops are best for the purpose?

What shall be done with the cream which rises upon the milk during the night, in cases where the Agitator is not used?

Grinding Curds—is it advantageous or otherwise?

Management of a good Butter Dairy.

Would the consumption of cheese be promoted in any considerable degree by the more general manufacture of small cheeses?

Condensed milk manufacture.

What is the best method for maintaining an even temperature in cheese-curing rooms?

Proper construction of cheese factories as bearing upon the quality of the product, as also with reference to convenience and durability.

Causes of tainted milk, and the remedies.

What have been the lessons of the past year?

Winter Milk.

Thomas Whitaker, of Needham, Mass., gives his method of treating stock in winter, and its results as follows: In winter I go to the barn at half-past five o'clock in the morning, rather sooner, perhaps, than a good many men would like to go. I give each cow a small handful of hay, and then go to grooming them just the same as I should a horse—first, the curry comb, then the corn broom brush, and then the hair brush—keeping them supplied with hay, a small quantity at a time, for about an hour. Then the boy milks. At night we fill a pork barrel with cut hay with which we mix half a peck of cotton seed meal, and half a peck of shorts. Upon this mixture we pour hot water, and cover with an air-tight lid. In the morning we pour on more hot water, and after milking this is given to the cows; at eight o'clock they are turned out to water; at noon, when the boys come from school, they are fed with hay, and at four o'clock a little more hay; they are then turned out to water. After which they are fed each a pailful of mangolds, rutabagas and carrots cut fine; then cleaned and milked, they each have about two quarts of cotton seed meal, corn meal and shorts—equal quantities of each; upon this boiling water is poured, to which cold water is added enough to fill a pail, with a little salt; after this a little more hay, and they are left for the night.

And now for the result. We sell one hundred and thirty-six quarts of milk a month; in November we sold fifty-seven pounds of butter, in December we shall sell about the same quantity, besides what we have for family use. This is from two cows and a heifer that was two years old last April, and calved the first of May, the other last September. We made butter all last winter, and shall make it all this winter. It pays better to make butter in winter than summer. Churning has never exceeded half an hour, and generally inside of that time. The milk is not scalded, but the cream before churning is brought to a temperature of about sixty degrees.

Selecting Milch Cows.

Hon. Charles L. Flint, Secretary of the Massachusetts Agricultural Society, delivered a lecture on the Principles of Breeding, at the Agricultural Convention at the Massachusetts Agricultural College, from which address we take the following extract:

I will not stop to discuss the indications of milking qualities, but simply to mention some of the most prominent. First, the milk-mirror, or escutcheon. Guenon, a Frenchman, whose life was passed among cows and dairy cattle, and who was a careful observer, discovered certain marks on the udder and its surroundings, which he called the escutcheon, and deemed an infallible sign of milking qualities. It consists in certain perceptible spots, rising up from the udder in different directions, forms and sizes, on which the hair grows upward, while the hair on the

other parts of the body grows downward. This turning up of the hair is an indication of the structure and tissues beneath, and if the mirror is strongly marked, by placing the hand upon it the veins and net-work may be felt.

The milk-mirror is one of the best signs of a good milker, but sometimes this mirror is possessed by cows of inferior quality. In such cases, the other signs of the quality will be wanting. We should find whether the cow possesses such marks as a large udder in proportion to the size of the animal, and soft, thin skin, with loose folds extending well back, of great extension when filled, but shrinking to a small compass when empty; large well-developed milk veins, especially the large ones under the belly, which should extend well forward to the navel, and apparently lose themselves in a cavity in the flesh, into which the end of the finger can be inserted. If the cow possesses these in connection with the mirror, she may be taken as a good milker. The escutcheon is found in young calves, and when found well developed, the calf should be preserved for the dairy.

There are a great number of external signs, which judges consider indications of milk, most of which are found to fail in individual cases; but a good cow should always have a strong constitution, as indicated by large lungs, which are in a deep, broad and prominent chest, broad and well-spread ribs, a respiration somewhat slow and regular, a good appetite, and if in milk, a strong inclination to drink, which a large secretion of milk almost invariably stimulates. In such cows the digestive organs are active and energetic, and they make an abundance of good blood, which, in turn, stimulates the activity of the nervous system, and furnishes the milky glands with the means of abundant secretion.

A bright, sparkling eye, but of peculiar placidness of expression, with no indication of wildness, but a mild, feminine look; small tapering, yellowish horns; small, thin neck, tapering towards the head; fore-quarters small, compared with the hind-quarters, and a thin, yellow, flexible skin throughout, are pretty sure indications of milk.

Butter Making in Kentucky.

In a late number of the *Rural New Yorker* we find the following statement of the views and practices of Mr. W. W. Ingram, who has been managing a butter factory at Winchester, Ky., for two years past: Presuming that the feed of the cows is of the best character, and that the milk is all right and has been kept at the proper temperature for getting the cream, the first thing to be attended to is

STRAINING THE CREAM—for the churn. The cream should be of uniform consistency when it goes into the churn, as it is difficult to make a fancy product when thin, thick and lumpy particles of cream are placed altogether in the churn. The proper way is to strain the cream into the churn by passing it through a strainer, so as to reduce it to an even or uniform consistency. For this purpose a pan, the bottom perforated with holes, is employed, and by thoroughly mixing the cream and passing it through this strainer, the cream is made all alike. Then, unless the cream is quite thin, water is added, in proportion of one-fourth the bulk of cream. The temperature is raised or lowered until the thermometer is from 60° to 62°. Then, when the churns are ready to be started, two quarts of warm water, having a temperature of 90° to 100°—but not above 100°—are added for every 16 gallons of cream. Now we are ready for starting the churns, and the dashers should not be made to go too fast nor too slow. Mr. Ingram thinks there is no churn yet invented (that he has seen) that will do so good work as the old-fashioned barrel dash-churn. He prefers this style of churn, and in churning, the stroke of dash should be regulated so as to make fifty strokes per minute. This is another point of importance in making a fancy grade of butter. A great many butter makers spoil their butter in churning, and have no definite idea how the churning should be done. From repeated and long continued experiments, it has been demonstrated that the stroke of dash should not be oftener than fifty per minute, in order to produce the best results. It is desirable that all the cream make butter at the same time. If it come unevenly, or particles of cream get mixed up with the butter when it is ready to work, the butter will be injured and will not keep. After the butter begins to come, add cold water freely, rinsing down the sides of the churn. Then when the churning is finished take out the butter from the churn and merely rinse off the buttermilk with cold water, using the ladle, and not allowing the hands to come in contact with the butter, even though they be "clean as clean can be." Of course it is understood that no one with dirty hands should have anything to do in the manufacture of butter. We do not want a dirty hand or a dirty foot within ten rods of our "golden bale" of butter. Now the rinsing having been attended to, the butter may be salted at the rate of an ounce of salt to the pound of butter, and be particular that your salt is pure. The factory filled salt, when obtained of the Syracuse Salt Company, or their accredited agents, is as good as the best. Work the salt in thoroughly and evenly, and do the working of your butter at this time. Then set aside in a cool place, and let it stand twenty-four hours, when it may be taken up, merely working out "the loose brine," and it is ready to pack.

At the Winchester factory the milk is set in pails surrounded by cold spring water so that an uniform temperature of from 50° to 60° is maintained. It stands in the pool of water for twenty-four hours, when the cream is removed. The cream is deposited in pails, which go to the pools, standing another twenty-four hours, or until it acquires a pleasant acid taste. It is then ready to be churned.

The Strippings

The last drawn milk, every dairyman knows, is the richest. It is important, therefore, to secure this by abstracting all the milk.

Besides losing some of the best and richest milk, there is another loss in not milking clean, as it has a tendency to dry up the cow, or lessen the secretion of milk from day to day. It is very difficult to impress milkers with the importance of drawing the strippings from the udder. Many milkers are in the habit of finishing their work just as soon as the free flow of milk ceases. Such milkers, it is needless to say, entail a heavy loss on the dairyman, in the course of the year, and if they milk many cows, they waste more than their wages. At this season of the year particular attention should be given to the strippings, especially in those cows which are not immediately to be dried off. The strippings make a very nice quality of butter, and some butter-makers think it pays well to keep them separate from the first drawn milk, setting in pans separately for choice butter. It is a little more trouble to the milker, perhaps, to separate the strippings, as it necessitates having a "stripping pail," but there is no doubt that it educates milkers to *milk clean*, if of no other advantage.

In conclusion, we say, be careful and secure the strippings; and as the subject seems naturally connected with butter-making, perhaps the following method of preserving butter, recommended by Mr. E. P. Wright, of Green County, N.Y., may be useful to butter makers:—

"Procure good white oak firkins that are perfectly brine-tight; take out the head (first making a small hole, say a quarter of an inch in size), then fill it with cold water; let it stand twenty-four hours before you are ready to use it; then rub, while wet, thoroughly with fine salt; fill your firkin as soon as possible. Your firkin should be of such a size that one can readily be filled in a week or ten days with sweet butter to within half an inch of the head; then place over it a clean cloth, and fill space with coarse salt; put in the head; then fill with strong brine, previously made of coarse salt, and stop it up."

Mr. Wright says that butter packed in this way, and kept in a cool place, will be as sweet in one year as when first made. —*X. A. Willard, in Western Rural.*

WASHING MILK CANS BY STEAM.—Homer A. Kidd, of Walden, Orange county, N. Y., writes to the Utica *Herald* that in order to get good, pure, sweet milk at his factory, he washes with steam all the farmers' cans, both night and morning. Forty quart cans are used, the same as are used on railroads to send milk to the city. He thinks this extra work pays fourfold, for he finds that he cannot trust the farmers to keep their cans sweet and clean. He has learned the importance of having good milk in making a prime article of cheese. With this washing of the cans, and the farmers having tin pails to milk the cows in, he gets the milk in much better condition.—*Prairie Farmer.*

MAN'S inhumanity to cows is often illustrated by abuse of the animal for restlessness caused by the pain inflicted in milking, by sharp finger nails. Mr. J. F. Furnam, Segel, Iowa, writes to the New York Farmers' Club, that one of his cows had always been very sensitive; but that after he commenced milking by clasping his fingers clean around her teats, so that his nails could not hurt her, she became gentle. Some cows will bear the pressure of the finger nails, and not resent it; while others will flare up on the first grasp, and knock the pail across the yard; then come pounding and kicking. Let us be careful with our cows, and not act without thinking.—*Prairie Farmer.*

Entomology.

The Codling Moth.

After a series of experiments, instituted the past summer, we have proved that, after all, the hay-band around the trunk of the tree is a more effectual trap for the Apple-worm than the rags placed in the fork of the tree. There is no superiority in the rags over the hay-band, unless the former are made to encircle the tree as thoroughly as the latter. Where rags are placed simply in the forks, many of the worms pass down the tree from the outside of the branches. If the rag is tied around the trunk, it will impede almost every worm that crawls down the tree from the fruit which hangs on, or that crawls up the trunk from the fruit which falls; and it then has a decided advantage over the hay-band, because it can either be passed through a roller or scalded, and used again.

It has been very generally accepted in this country that the Codling Moth is double-brooded, and in all our writings on the subject we have stated it to be so, though no one, so far as we are aware, ever proved such to be the case beyond a doubt. Mr. P. C. Zeller, of Stettin, Prussia, informed us last winter that it is only single-brooded in that part of the world, and Harris gives it as his opinion that it is mostly so. Now, such may not improbably be the case in northern Prussia, and the more northern of the United States, though we are inclined to believe otherwise. At all events, this insect is invariably double-brooded in the latitude of St. Louis, and its natural history may be briefly told as follows:—The first moths appear, and begin to lay their eggs, soon after the young apples begin to form. The great bulk of the worms which hatch from these eggs leave the fruit from the middle of May to the middle of June. These spin up, and in from two to three weeks produce moths, which pair and in their turn commence, in a few days, to lay eggs again. The worms (second brood) from these eggs leave the fruit, some of them as early as the first of September, others as late as Christmas. In either case they spin their cocoons as soon as they have left the apples, but do not assume the pupa state till towards spring, the moths from the late matured worms appearing almost as early as those from the earlier matured ones. The two broods interlock, so that in July worms of both may be found in the fruit of one and the same tree. We have repeatedly taken worms of the first brood, bred the moths from them, and obtained from these moths the second brood of worms, and we have done this both on enclosed fruit hanging on the tree in the open air, and on plucked fruit in-doors. In the latter experiments the moths would often cover an apple with eggs, so that when the worms hatched they would enter from all sides, and soon so thoroughly perforate and devour the fruit as to die of starvation. This is a clear case of misdirected instinct in the parent, caused doubtless by confinement.

From the foregoing facts it becomes obvious that the rags or the hay-band should be kept around the tree, say from the first of May till the fruit is all off; and to be thoroughly effectual, the insects collected in or under them should be destroyed regularly every fortnight during that time.

Destructive Grain Insects.

After a man has fought insects all summer and succeeded in saving his crops, it seems to be no more than a just reward for his labours that he should rest in peace during winter. Usually our pestiferous insects remain quiet during cool weather. There are, however, a few rascals who occasionally creep in among stored grain, and do considerable damage. Farmers in the extreme Northern States suffer less from grain-eating insects than those farther South; and this should console them for the long winters and severe cold weather. Every locality has its advantages and disadvantages, and we doubt if there is really much difference; blessings are showered upon us wherever we go, although it is not human nature to see things in such a favourable light.

We have at the North injurious insects in abundance; but at the South they are far more plentiful, and their season of rest is of very short duration. Insects injurious to stored grain are seldom very destructive in cold climates, unless brought from a warm locality and then placed in a favourable position for continuing their depredations during winter. The common Pea Weevil (*Bruchus pisi*) is probably the most destructive and wide spread of any of this class of insects; but to this there is a northern limit, which, luckily, is south of the highest latitude where peas will grow; hence, we do receive clean, unaffected seed from Canada and the northern countries of Europe.

Until within a few years past, beans have been almost entirely exempt from the attacks of insects, particularly in the Middle and Northern States; but that time is past, and our farmers will have to look sharply and fight vigorously, for an enemy has appeared that will make sad work among beans in favourable localities. This Bean Weevil is not a new insect, for it was described many years ago by that eminent American Entomologist, Thomas Say, and it is known as *Bruchus obsoletus*. It is a very small beetle, not as large as the pea weevil, but similar in form. They do not appear to have much choice of kinds, as they attack the Lima, Black Wax, and all of the choice sorts, a half dozen weevils being often found in a single specimen. We are informed that in Philadelphia, and cities farther South, it is almost impossible to find beans raised in the locality that are not affected by this pest. If the beans are stored in a warm place, the weevils come out during autumn and winter; and we have seen bushels of various sorts of beans within the last few weeks that were entirely destroyed by this pest.

In white varieties, like the Lima, the weevil can be seen through the outer skin before they make their appearance, and affected specimens may be rejected; but with the dark-skinned sorts this cannot be done, and a close and careful examination is necessary.

We would advise every one who purchases seed beans to examine them closely, and if a weevil is found, reject the whole lot, or place them in a barrel or tight box, and keep them there until the insects begin to come out, and then fumigate with sulphur, or pour a little kerosene among the beans and close up the vessel tightly until all the bugs are dead. Many thousands of dollars' worth of beans have already been destroyed this season by the bean weevil; and it is the duty of every man to aid in preventing their increase and dissemination.

THE CORN OR ANGOUMOIS MOTH.

This very destructive insect is known in Europe as the "Angoumois Moth," receiving its common name from the French province of Angoumois. It is known to Entomologists as *Butalis cerealella*, of Olivier, and was described in a work published in Paris in 1762. This pest has now become very abundant in many localities in this country; at least we judge that to be the case, from specimens of grain infected with it received from various sections. It appears to prefer Indian corn, although it will attack wheat, rye, barley, and in fact all of our common cereals. Sweet corn appears to be its favourite food, and our seedsmen are already suffering severe losses from its ravages, although we suppose few of them would be willing to admit that such a a great pest could be found in their establishments.

We know, however, that this grain moth is wonderfully abundant, and our object in mentioning the fact is to put the farmer on his guard against such a formidable pest. Harris says of this moth:—"The Angoumois grain insect, in its perfected state, is a little moth of pale, cinnamon-brown colour above, having the lustre of satin, with narrow, broadly fringed hind wings of an ashen or leaden colour; two thread-like antennæ, consisting of numerous beaded joints. It lays from sixty to ninety eggs, placing them on a single grain; from these are hatched, in from four to six days, little worm-like caterpillars not thicker than a hair. These immediately disperse, and each one selects for itself a single grain and burrows therein."

Knowing the habits of this insect, we can readily destroy it by fumigation when first discovered, and thereby prevent its increase.

ANOTHER GRAIN PEST.

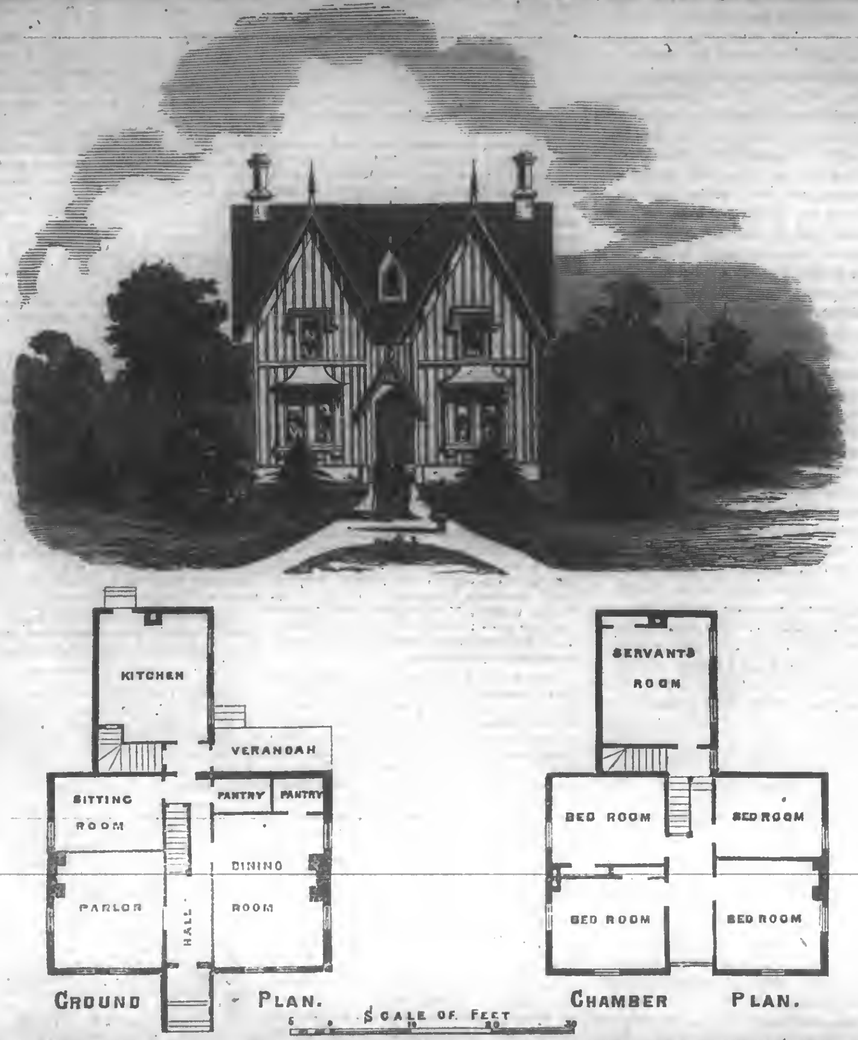
The true grain weevil of Europe (*Silophilus granarius*) has become fully acclimated in this country, and destroys hundreds of bushels of grain annually. It is a very small, slender-snouted beetle, not more than an eighth of an inch long and about one-twentieth broad. To the naked eye it looks black; but when placed under a glass its colour appears to be dark brown, with a slightly punctured thorax. This little pest, both in its larva and perfect state, destroys grain of various kinds; and a few days since we found millions of these beetles feeding upon a quantity of corn stored in this city.

Harris states that the female deposits her eggs upon the grain after it is housed, and the young grubs hatched therefrom immediately burrow in the grain, the substance of which they devour. These grubs undergo their transformation in the grain, and do not leave it until the beetle has come to maturity. This is one of the greatest pests that has appeared in this country, and it will be one of the most difficult to get rid of, for it keeps buried in the grain during nearly its whole period of existence. It is said that kiln-drying the grain will destroy the weevil, but this would also be very likely to destroy, or very much injure, the vitality; and for grain kept for seed, the practice could not be recommended.—*R. New Yorker.*

Architecture.

Design of a Small Farm Dwelling.

Once more we present our readers with the plan of a small picturesque frame house, simple in design and capable of being carried out at a comparatively small cost. The ground



of the house, communicating with a lobby in the rear. Connecting with the kitchen, on the right side of the main hall, is a dining or family room, fourteen feet wide by seventeen feet long, having a pantry opening ont of it at the end. On the left side of the hall is a parlour and sitting-room, which, if necessary, might be used for a bed-room. The parlour is fourteen feet square, and the sitting-room is fourteen feet long by ten feet wide. The store pantry is at the end of the hall, and near the kitchen. The ground floor ceiling will be ten feet high, and the first floor nine feet six inches high. The first floor is divided into four good large bedrooms, and two wardrobes.

There are fireplaces in the dining room, parlour, and best bed-room upstairs.

On account of the steep pitch of the roof, there will be room for four good bed-rooms, which could be fitted up at some future time if not required at first. The building is to be framed in the usual way, but instead of supporting the sills on cedar posts, either brick or stone piers are recommended, or what is better still, a good stone or brick wall foundation. A frame set on a stone or brick foundation will be sound and good when one set on posts would be cracked and twisted, and nearly used up. There will be a cellar under the kitchen, the walls of which are to be of stone. A concrete floor,

when good drainage can be obtained, is preferable to planking.

The exterior of the frame is to be sheeted with 1¼ inch tongued and grooved upright boards, and the joints covered with a 1½ inch champhered batten. In order to make the house warm, the inside of the frame might be sheeted with common rough tongued boards, and then strapped and lathed and plastered. The plastering in all cases should be carried down to the floors. The roof is to be shingled with good shingles laid in hair mortar.

The exterior of the building should be painted some nice fawn or light buff colour, with anti-corrosive paint, as it will last four times as long as the common lead paints. It is now used in all the Government buildings in Great Britain. It can be had in any tint except pure white.

No description of the exterior is needed, as the drawings speak for themselves.

The interior finish of this house can be either plain or ornamental, at the option of the builder. The woodwork, if neatly executed with clear dry lumber, might be simply varnished with good effect. There are many beautifully grained pieces of pine, which, if well selected, and put in the panels of the doors, would look as well as many of the expensive hardwoods. The mouldings might be variegated with butternuts or walnuts with very little additional cost. But these matters, though small in themselves, give elegance and style to a house, and proclaim the man of taste. We advise any of our readers, who contemplate building, to try this, and we are sure their architects will heartily aid them in carrying ont their ideas in an artistic manner.

This house, if completed in the ordinary style of finish, could be built for about $1,200.

How to Avoid Wet Cellars.

An excess of water, or too much dampness, in some instances, arises from surface water, and in others, from spring veins that crop out in the cellar. In many instances, when the excavation is being made for a cellar, in a heavy, springy ground, water-veins are cut off two or three feet below the surface of the ground. When such is the case, the water in those veins will be discharged behind the cellar wall, and will settle down and pass along on the surface of the cellar bottom. Sometimes, however, the veins of watar are not reached till the excavation is about completed. Then, when the water veins, which pass through the earth like the blood veins through the body of a living animal, are filled with water, the bottom of the cellar will often be covered with water, even when a good underdrain has been provided to convey it away as soon as it has accumulated in sufficient quantities to flow out through the underdrain.

Now for the remedy. The correct way to avoid a wet cellar, is to lay a tile drain entirely around the outside of the excavation, nearly a foot lower than the bottom of the cellar, before the foundation walls are laid. But after an edifice has already been erected, and water appears on the cellar bottom, the most satisfactory way to render the bottom dry is to sink the channel nearly a foot deep entirely around the cellar close to the wall. and lay a course of drain-tiles in the bottom, which will cut off all water-veins, and thus render the cellar quite satisfactorily dry, by conducting the water into the tiles before it can work along toward the middle of the cellar.—*Scientific American*

Repairing Buildings.

An advantage is always gained by the farmer who is fully prepared for cold weather when it comes, and economy is not only exercised in properly securing fall crops, but in putting his buildings in such condition that they shall give full protection against the strong winds and driving storms of winter. Hardly any building is so good that no attention in a mechanical line is needed. An absent shingle upon the roof should be replaced as soon as its absence is discovered, for if not, leakage and decay are sure to follow. Where a shingle has been removed by wind, it may be known that those immediately above and below are not securely nailed, and soon a breach of considerable magnitude will be made—a nail in time will save nine.

Another important thing to notice in connection with the roof is the condition of the ridge-boards. In travelling through the country, hundreds of outbuildings and many residences may be seen with these entirely or in part gone. The opening not being large, but little snow or rain falls through, and does not attract particular attention, but yet the moisture so completely penetrates here that the ridge-pole, ends of the rafters, and roof-boards decay. One hour's work a year will keep everything as it should be.

When the weather-boarding of buildings gets to clattering, it should be nailed up at once. The best way is to take a hammer and pocket-full of nails and give each building a looking over, twice a year, say fall and spring. When a board is allowed to drop off, it soon warps up, or splits in such a way as to be unfit to replace, and new timber has to be used to make the repair.

If stable floors, feeding racks, and mangers need repairing or making new, the time to do the work is before wanted for use. If neglected until the season for stabling stock, the cold weather and press of business will very likely prevent further outlay than patching up so as to do for the present, resulting in inconvenience to the flockmaster, loss of feed by waste, and discomfort to the stock all winter.

During the pleasant weather of October, a good time is afforded to paint buildings. At this season of the year, flies, dust, and the scorching heat of a summer's sun, are not to be contended with. Our experience has been that paint applied in dry and not over hot weather is much more durable than that put on in and exposed to the hot sunshine.

Poplar is of little use until thoroughly seasoned, as it shrinks greatly.

Size of Building Timber.

Many years ago, when good timber was so abundant that a large sill or beam would cost no more than a small one, builders were apt to estimate the strength and firmness of a frame structure by the size of the timbers. If a barn or dwelling, for example, were constructed of large and heavy timbers, it was thought safe to assume that the edifice must be a strong one. But as builders came to study the strength of building materials, they found that the stiffness of a framed structure was dependent on something else than the size of the timber. To illustrate by a practical example, we will suppose that the sills, one foot square, are allowed to rest on the top of a strong foundation wall. Gains for the ends of the joists are usually cut in the sills, so that the timber beneath the joists is simply equivalent to a thick plank, so that there is nothing gained, but much loss sustained, by employing a very large sill, and divesting it of a large proportion of its strength by making numerous gains in one side. The strong foundation wall does not require the additional strength of a large sill. If, instead of a large stick of timber, a joist or plank, say two to four inches in thickness, be employed, having the joists extend entirely across its upper surface, so that the ends will be flush with the face of the wall, the construction will be better in every respect.

1. There will be a saving in the expens for lumber. 2. The timber can be carted and handled more economically. 3. The expense will be reduced more than one half. 4. The structure will be generally as strong and just as satisfactory, as if large timbers were employed. When the ends of large joists enter a gain only two to four inches, any considerable thrust of one or two of the joists against the sills will start the ends of all the joists out of the gains, as there will be nothing to hold them except friction, since nails are not usually used when joists are let into gains in the sills, But, when the joists extend over the surface of the sills to the face of the foundation wall, and are secured with nails to the sills, it will be almost impossible for a superstructure to spread.

Another consideration of no minor importance is, regarding the proper depth of joists proportionate to their length. When joists sixteen or twenty feet long are required, builders seldom enter into any calculation as to how deep they should be. As a rule, joists eight or ten inches deep are provided; whether a room is ten, fifteen or twenty feet broad, while there may be much economy exercised in the size of the joists, by careful attention to the strength of the materials employed, and the strains to which they are exposed. The rule for determining the proper and economical depth for joists is that the depth must increase as the square of the distance from the point of support on the wall. If a joist sixteen feet long, for example, were eight inches deep, the chief point to be considered in the strength of the materials is, whether a timber of that depth, eight feet from the point of support, will have sufficient strength to resist the superincumbent pressure.

A joist eight inches deep, of a given length, may sustain a ton without any deflection. But let the length be increased to sixteen feet, and the same weight, unless the joist were of superior timber, would crush it at once. Want of attention to these points has led to the construction of buildings in which, when the walls were far apart, the joists were quite inadequate to the superincumbent pressure.—*Technologist.*

Poultry Yard.

Birmingham Poultry Show.

The annual show of poultry at Birmingham, which takes place simultaneously with the cattle show at Bingley Hall, came off this year with its usual *eclat*, and though not quite equal in the number of its entries to those of 1867 and 1868, the largest on record, it surpassed by more than a hundred pens that of last year. The total number of entries was 2,578. There was a slight falling off numerically in Dorkings, as compared with last year, while in Cochins, Brahmas, and Game there was a considerable increase. The Game and white Cochins were a remarkably good class; the Buff Cochins were good, though not up to the Birmingham standard, and we are sorry to note the existence of the most reprehensible practices which too often disgrace poultry shows, as indicated by such criticisms as the following from the London *Field* :—"If the Judges had disqualified all the cocks with their tails pulled there would have been a great alteration in the prize list." Anything like trickery should always be a disqualification for the time being and ever after, we should say. Of the light Brahmas, the *Field* says :—"They were remarkable. In the first place the arrival of the specimens from America caused a flutter of excitement, as English breeders wished to see the standard there in vogue. Mr. Simpson's specimens were very large fine birds, necessarily suffering from the voyage, which told on them in the matter of condition. Their defects, judged by our standard, were that they were too creamy in colour, somewhat too leggy, and a little deficient in pencilling on the hackle; but they held their own most creditably, and deservedly found their place in the prize list in despite of the drawbacks of the voyage. The gem of the light Brahmas were Mr. Crook's pullets; one, if we dare use the term, was absolutely perfect." The French fowls were "magnificent." The largest class was that of Game, numbering 374 pens. The specimens of Dominique from America excited considerable attention. The following are the weights of some of the principal pens :—Ducks, white, Aylesbury, drake and duck, first, 18 lbs. 9 oz.; second, 18 lbs.; third, 17 lbs. 16 oz.; fourth, 18 lbs. 4 oz. Rouen, drake and duck, first, 9 lbs. 4 oz.; second, 10 lbs. 6 oz.; third, 18 lbs. 2 oz.; fourth, 17 lbs. 4 oz. Geese, white, exceeding one year, gander and goose, first, 58 lbs. 12 oz.; second, 56 lbs. 5 oz.; ditto birds of 1870, first, 49 lbs. 4 oz.; second, 49 lbs. Gray and mottled gander and goose, exceeding one year, first, 62 lbs. 6 oz.; second, 54 lbs. 6 oz.; ditto, birds of 1870; first, 53 lbs. 6 oz.; second, 49 lbs. 1 oz. Turkeys, cocks, over one year, first, 36 lbs. 4 oz.; second, 35 lbs. 2 oz.; ditto hatched 1870, first, 24 lbs, 6 oz.; second, 23 lbs. 12 oz.; hens, exceeding one year, first, 31 lbs. 4 oz.; second, 29 lbs.

Correspondence.

Farming as a Profession.

To the Editor.

SIR,—It is frequently the subject of remark that the sons of Canadian farmers abandon the calling of their fathers for modes of life less laborious, and, in their opinion, more respectable. Perhaps, as the subject is important, you will allow space for a comparison between the practice of agriculture and some of these very much more dignified pursuits.

Commencing with the three learned professions—Law, Medicine, and Divinity—we may notice that in none of them, judging by the successful, can the hope of rising above mediocrity be indulged, unless some years be devoted to earnest, toilsome, and expensive studies, and, these past, what is the prospect?

In Law. Were the object of law and of lawyers always the impartial administration of justice, a worthy ambition might well inspire the novice with hope to excel in such a noble profession. But will he never find the court of law an arena where subtlety—craftiness—chicanery—are recognized weapons and armour, which he must adopt, or combat at disadvantage? Will he not be expected to use every means to persuade judges, cajole juries, and browbeat witnesses? Can he always choose between brief and brief, and refuse to advocate the cause which his heart suspects to be unjust? Will he not be surrounded with temptations, environed with inducements to become a mere legal mercenary—a purchased free lance—ready, if gold be also ready, to fight the battle of might against right, assist the powerful to bear down the helpless, and aid the criminal to evade punishment? And at the best, supposing all these degradations avoided, he must expect his health impaired by the confinement of offices and the contaminations of court-rooms, his temper soured by the opposition of rivals, and his mind warped by a lifetime passed in petty and vexatious disputation.

In Medicine. The practitioner may expect—nay, must even hope—his slumbers disturbed, his meals interrupted. Day and night, in all seasons and in all weathers, he must, in caring for the health of his patients, be careless of his own. And though he be skilful, laborious, and charitable, how frequently are his abilities decried, his good faith questioned, and his most humane actions ascribed to mere greed of reward. Master the resources of science as he may, how often must he endure the mortification of finding the ignorant empirio preferred to himself? He may—often does—after many years of toil, attain wealth and position; but, as in all overcrowded professions, the blanks are many, the prizes few, and those few scarce worth the labour necessary to secure them.

In Divinity. In this field there are not—there cannot be—too many labourers; but as none should, so none need, enter it with the hope of obtaining ease, or the view of amassing wealth. He whose talents can secure him those in this employment, could, in others, have obtained more. Of all men of education and refinement, the clergyman is, perhaps, the hardest worked and the worst paid.

I might speak of the merchant, steadily pursuing the phantom of wealth, bending over his books, and spending his life in the dusty counting-house—of the manufacturer, living amid the smoke of coal and the din of engines—and ask whether these lives are preferable to that of the farmer. Why, they themselves, if asked, frequently answer that they hope one day to retire, and spend the evening of life amid rural scenes, amusing themselves in the cultivation of a farm. For the farmer to leave his occupation for theirs, then, would, not improbably, be to return to it when vigour and strength are gone, and he can no longer enjoy it, or, at most, only experience the poor satisfaction of hiring others to do that which he once had pleasure in performing himself.

And, leaving these, let us ask what is the present, and the probable future position, of the Canadian farmer? In the past, he suffered great disadvantage. Raising little but wheat, which had first, with great difficulty, to reach, and then to cross the ocean before finding the market, he exhausted his land, and invited the attacks of insects by the yearly increasing weakness of the growing plant, in endeavouring to raise that which alone he could sell, and which he must sell, to live. But now, all that his dairy can produce or his fields grow, and every head of cattle he can fatten, find ready sale in Canadian, American, or European markets. He will soon carry produce thither much more cheaply, by the network of railways, either now built, building, or projected, which will intersect the whole country; and by canals, which on the completion of their intended enlargement, will allow the transport of freight in unbroken bulk from Superior to tidewater, and to Europe itself. He has paid over-high wages; the tide of emigration set to the States. It has now turned, is flowing to Canada, and will soon give him cheaper labour, and a broader home market. He formerly sent to Europe and to the States for his clothing and his tools. Now, Canadian looms weave fabrics little inferior to those of France or Scotland; and Canadian artisans form, from English iron, tools far superior in shape and temper to those they imported from England, and will soon make yet better ones, when Canadian iron (far better than average English) is available. When we remember, also, that scientific farming here is in its infancy—a mine of wealth which the farmer has never explored; that he has yet to practise and benefit by the methods adopted in other countries—the management and removal of surplus moisture from the soil—the admixture of different earths—the employment of waste substances as manures—the obtainment of shelter and climatic advantages by plantations of trees—it is not too much to expect that the average position of Canadian farmers, if not approaching affluence, will be, at least, one of complete independence.

The Canadian farmer now holds the very position in which the sages of Greece and Rome strove to maintain their rural populations. While those populations held that position, they preserved their liberties, for its occupance rendered impossible the existence of the luxury, effeminacy, and corruption, which destroyed those great nations. That safeguard is formed by such division of land as, giving many a liberal portion, gives few a very large one. The freehold tenure of this land secures the farmer from the political pressure often exercised by landlords elsewhere, and supports, perhaps, the most free and independent constituencies in the world, consisting of bodies of electors too deeply interested to be careless; too wealthy to be bribed, and who may be, if they wish, too well-informed to be deceived, by unscrupulous politicians. In a country destined to be principally agricultural, the votes of these constituencies will always outweigh the less pure suffrages of the towns, given by men less interested, and more accessible to pecuniary influence. In these words is expressed a great fact—that the Canadian farmer, if he choose, may govern, as he chooses, the country wherein he dwells. In so doing, no man makes him afraid. He is not, as in Continental Europe, awed by governments and dynasties; nor, as in the British Isles, influenced by powerful individuals; nor, as in the United States, outvoted by those who possess neither property nor education. This power is no slight one. His country is one of great resources and vast possibilities, and, well directed, may become, socially, commercially, and politically, one of the first in the world.

There is neither profession nor calling more dignified than that of the agriculturist; and if, in any respect, others are his superiors, it is simply in point of education. To rival, or to surpass them in this, it is not necessary that he adopt their mode of life. Surely, the book of knowledge is not closed to the farmer. Comparing his manner of life with that of the non-farming community, the health and comfort he generally enjoys—the pleasures enjoyed by those of his avocation alone—the delights of a life passed amid the beauties of nature, in the pure air and bright sunshine—will suggest themselves to all. And it may be remarked that the farmer appears under the peculiar care of the Almighty. Of other callings the Scriptures say comparatively little; of that of the farmer they speak everywhere, and everywhere encouragingly. To him is given the earth, as a manufacturer with whom to deal—one who asks but the refuse, and gives in return the most beautiful and the most valuable. He is surrounded with guides, with assistants, with warnings. Mighty and powerful agencies are his servants. The sweet influences of the seasons—the refreshing showers, the ripening sun—all elements of air and water, earth and sky—labour incessantly for him. His calling is the most important, because the most useful—the most noble, because the least dependent. Luxury and weakness are the offspring of cities; but the fields and the woods are the birthplace and cradle of strength and manhood. From the flock God called David—from the plough Elisha. From the plough, to save his country from foreign thraldom, came Cincinnatus; and to it, his task accomplished, he returned, despising, compared with his rural life, all the wealth Rome could give, and all the honours her senate could bestow.

The Canadian farmer comes of a nation unrivalled for perseverance and determination. There are those of his race who have, generation after generation, farmed in the same name the same lands for eight hundred years. Successful agriculture is the basis of all national greatness. Spaniard and Portuguese, Frenchman and Hollander, have in turn overrun and claimed sovereignty in all the vast domains of Australasia—the immense regions of North America; but their places know them no more, for the Anglo-Saxon has subdued and holds the land by the force of the plough. By it the farmer of Canada has subdued broad and fertile regions. He has yet broader, yet richer, to possess. Were it not better that he continue to pursue his own occupation, rather than exchange it for others more ignoble, or less agreeable, in which he may secure greater wealth, but in which he will find less pleasure—in which he may obtain more consideration from the ignorant, but not greater esteem from the wise? May he not obtain greater happiness, perhaps greater prosperity and higher distinction, if he remain on the land God has given him, cultivating it with the perseverance and success of his forefathers, doing, as they did, his duty by the land, and determining, with sturdy honesty of heart and purpose, to leave it to his successor better than he himself found it?

R. W. PHIPPS.

Toronto, Jan. 2, 1871.

TO CORRESPONDENTS.—We would once more repeat one or two hints to our correspondents—write briefly, legibly, and on one side of the paper only. In making enquiries, do not mix up a variety of subjects. Do not, for instance, send a string of queries in horticulture, entomology, cattle diseases, &c. Write each question separately.

Encourage the Boys and Girls.

To the Editor.

SIR,—We farmers in Canada are too prone to consider our own claims on our children, rather than deal with them as we would probably like to be dealt by. Our sons are expected to remain contented on the farm, working for bare food and clothes until they are twenty-one, and then they are allowed to begin for themselves. They naturally feel that, up to that age, all they have ever got by working on the farm is entirely deficient in encouragement, so far as it is likely to reconcile them to the same course of life; and they also feel they are fit for nothing else. They have not education or business knowledge to enable them to go to some other avocation, and consequently are dissatisfied with the past and quite undecided for the future; and this feeling applies not only so far as their prospects of ultimately possessing a farm of their own goes, but causes them also to be quite undecided as to the advisability of following agricultural pursuits at all. The consequence is that we continually hear the parents say, "Our boys are going away to the States, and cannot content themselves on the farm in Canada." The father has never done anything to make them contented here or on the farm. The boys rarely have any good clothes, and still more rarely any money, and what clothes or money they have had has (with the exception of the most ordinary clothing supplied at home) been the result of working out for some one else, who has paid them for their labour the same as they would have paid any other hired man. This course is bad in every way.

Young men, about the time of what is called coming of age, naturally wish to marry and have a home of their own; and experience has shown that all such ought to marry and settle in life if healthy and inclined to do so; but at the same time they must have something more than the wife—which certainly usually can be obtained for nothing. Such is not the case, however, with farm stock or furniture; all this must be bought and paid for, or obtained on credit, and these very debts so contracted generally cause a sour, unpleasant, and often regretful feeling at ever having married at all, and a wish that they also, like some other neighbour's son, had moved away to some other country or locality, where no thought of marrying or home could from circumstances have been entertained, and where all their earnings could have been expended on themselves. These instances of leaving home and obtaining employment elsewhere, rarely ever end well. They never, or very seldom, do result in anything like a home far away; but the young man moves from place to place, usually with plenty of money for absolute necessaries, but with expenses naturally much increased; and he generally ends after 10 or 15 years' absence, with a return visit to the old home-

stead; having accumulated much knowledge of the evils of such a kind of vagabondish life, and any quantity of insight of taverns, tobacco, drinking, and generally gambling experiences. If he now marries and settles at home, as he often does, he is a pest; and usually demoralizes all the young men who are, like himself in former years, unsettled in their future prospects. In the relation of his fifteen years' absence, of course, there will be much to amuse and interest such hearers in these recitals. In these tales he rarely relates the pains and difficulties he had encountered, or if he does, they afford only the more interest and excitement to the audience.

Now this is true, and thousands know it to be true, and regret when too late that they did not cause the boy, when yet young, to have an interest direct in all that was done on the farm, or at least in something that was continually being raised or provided for him, to be appropriated to his use when the time comes for him to require them. To do this will absolutely pay the father well; for every young man of, say 18 to 23, is worth $120 to $140 a year and his board, and five years of this saving would accumulate $600; and any lad would consider himself rich with such a sum, and, in fact, would not desire to have so much laid by for him; and to avoid temptations this amount need not be in money, but can be paid in cattle, teams, beds, bedding, and a variety of necessaries, all of which can be raised on the farm, and to which for the most part the son's own exertions have mainly contributed. The same principle applies to girls. They must have nice dresses; others do, and they must, or they will at once hire out to those who will not require them to work any harder, and who will pay them sufficient to obtain them. We all know that sometimes on a farm there is little enough to sell to make both ends meet, even where all is sold that can be sold; but we also know that under such circumstances, all grown up children who are able and willing to work, see just as well as we older people—that there must be something wrong somewhere or their labour must be unprofitably applied; for if they hire with some other person they can get plenty of necessaries, and whilst they remain at home their labour is absorbed and they cannot do so.

C.

Crops in Sidney—Fall Ploughing, &c.

To the Editor.

SIR,—It is rare that we can plough so late in the season as now, Dec. 10. We have had scarcely any winter weather. To-day the weather is as fine and warm as in early September. There has not been much interruption to Fall work, and therefore a great deal has been done, especially in ploughing. The value of this operation at this season depends, I think, upon the character, situation, and condition of the soil. Heavy, tenacious clays are benefited, because the alternate freezing and thawing tend to pulverise and set loose the constituents of the soil, and they are in a condition to receive and retain moisture, so much needed in such soils. Early fall ploughing is of value to all soils, when the intention is to plough them again in the Spring, unless on hill sides or in places exposed to the action of the Spring freshets; for in that case, much of the valuable surface soil would be carried away and lost. Clover soil I would prefer to plough as late in the Spring as I could, allowing the grass to start, and thus add to the fertility of the soil. If land could be ploughed early in Fall, and sown to field turnips or rye, it would be better, thus affording pasturage at a season when it begins to fail.

Crops in this vicinity were not so good as we anticipated, the yield being light. Clover for hay was almost a total failure, although the second growth will afford some seed and fodder. Experience proves that a varied husbandry is better than depending exclusively upon one crop. What little fall wheat was grown has yielded well.

There is a kind of mania for barley raising at the expense of other cereals. It is surprising that men can expect all kinds of soil, in all sorts of conditions, to raise this crop. From a little more than six bushels sown I had 103 bushels, while many had far less from double the quantity. It was grown, after clover, growing peas first, then barley. My rotation would be, when possible—1st, clover; 2nd, peas; 3rd, barley; 4th, corn, potatoes, or roots with all the manure applied to them, or a crop of buckwheat ploughed under and another sown, succeeded by summer fallowing for fall wheat, seeded to clover. By this course, the soil would be kept in health.

Fall wheat has attained a very rank growth on this Trenton limestone soil, being upwards of a foot high? Some say that pasturing it is an injury. Is this so? I know I would rather have meadows unpastured late in the Fall.

The errors of much Canadian agriculture seem to me to be, 1st. Too little thought for the future, like a traveller starting on a journey, who makes his horse do all he can at the outset, to be exhausted before the journey's end. Borrowing of the future to pay the present, and every loan principal. 2nd. Want of proper rotation; and a better tenant system. 3rd. Want of community in farming. Every neighbourhood should be a sort of agricultural bank, in which each farmer should be a share-holder. Machines, stock, and grain of the best quality should be had at some one place. If each farmer were given his share to do in this way, all would be benefited, and a man could find a good stock animal in his own neighbourhood. The club system would pay. 4th. The education of farmers' sons does not, in general, fit them for the discharge of their future employments. To many the book of nature is a sealed book, while they may know everything about other books. 5th. That false idea of wealth, which is not contented with a substantial sufficiency, but asks for more acres, instead of in principle doubling the acreage of fertility they already possess. 6th. Hoarding and loaning surplus capital, instead of expending it in useful improvements, affording employment to labourers.

Upon the whole, however, farmers are progressing. When they see it to be their interest to invite immigrants to comfortable dwellings and conveniences upon their farms, thus insuring permanent and reliable help, one great step in advance will be taken.

The circulation of practical agricultural information by papers and otherwise, the settling amongst us of immigrants of the true stamp, the introduction of labour-saving machinery, the dairy system, the building up of our cities and towns in manufactures, &c., and the work of the true teacher and minister are doing much for the weal of the farmer, and tending to elevate him and his profession.

The immigration of boys and girls, with the proper safeguards, will do much for the country; but if more from the agricultural districts could be brought out, it would be better; or give those who do come a preparatory training. There are too many false ideas about the country in their heads; they have to be educated over again in many cases. They need to be taught self-reliance, and not dependence upon those who employ them or bring them out; however, they soon learn and become useful.

H. LE BOUTILIER.

Sidney, Hastings.

Leached Ashes for Sugar Beets.

To the Editor.

SIR,—I have recently purchased a farm of 300 acres, the land of which is well adapted to raising roots of the ordinary kind, and in the spring I intend putting in a few acres of sugar beet, provided I can obtain the seed, and would be greatly obliged if you would give me your opinion as to whether leached ashes, of which I have a great quantity, mixed with barn-yard manure, would make a good dressing, and if so, in what proportion. People here tell me that ashes will prove injurious, unless the quantity be very limited.

O. C. H.

REPLY.—We would not advise the use of ashes for this crop, as the presence of potash even under ordinary circumstances, is injurious, and it is one of the constituents to be avoided and dealt with individually in the manufacture of beet sugar. The seed of the most reliable sorts can be obtained here, provided orders with reference or cash be forwarded at once to the wholesale seedsmen of this city—James Fleming, Charles Dawbarn, or J. A. Simmers, all in the wholesale importing seed trade. Your best course will be to use good deeply cultivated rich loamy land, without manure, as a trial. The great object being to produce *sugar in the beet*, not by any means the largest roots, nothing but absolute practical trial with various kinds of the sugar beet seed, and an absolute test of the different sorts in producing sugar, will enable you to act with safety. This course has been found advisable again and again; and small beets, sometimes, with the best kind of soil, will produce double the sugar that large roots will, under adverse circumstances of soil and seed.

Land and Farms for Lease.

"An English Yeoman's Son" wants full particulars on the subject of the value of wild land, and also of cleared farms, west of Toronto; also whether farms can be rented, and at what rents.

Wild land, near any of the present lines of railroad, except those built last year, is worth from $15 to $20 an acre, if of the best quality. If otherwise, and the land is wet or poor, from $6 to $10 an acre.

Cleared or partially cleared farms are worth from $20 to $30 and $40 an acre, according to buildings and situation. The cost of clearing land is usually about $16 an acre, and includes fencing.

There are farms to be rented, west of Toronto, in great numbers, caused by family circumstances, death of elder members, or other casualties. The rent is from $2 to $3, and sometimes $4 per acre, for the cleared—no charge for that uncleared—according to buildings. An advertisement in the GLOBE or CANADA FARMER would obtain answers, provided it were inserted a reasonable time.

It is impossible to extract green stumps. You must wait six years for them to decay out. We refer you to the back numbers of the CANADA FARMER and articles on "A Backwoods Farm," for further information. Every word of those articles is based on personal experience.

INFLUENCE OF FEED ON MEAT.—A "subscriber" asks "whether the quality of meat is affected by the kind of food given to the animal," and particularly if the turnip flavour, so noticeable in the milk of cows fed on this root, would impart a similar flavour to their meat? Most assuredly will the quality of the flesh be materially influenced by the kind of food that has been used, and the flavour and odour of turnips are sometimes very perceptible in the meat of animals that have been exclusively or largely fed on them, more particularly if the beast be killed soon after a meal. We once purchased from a neighbour a hind quarter of a cow that had been choked while eating turnips, and we shall never forget the strong turnip taste that persistently clung to that beef, in spite of salting, and every conceivable mode of cooking devised to overcome the obnoxious flavour.

NOTICE.—Our readers are specially requested to take notice that this number of the CANADA FARMER is sent free to all subscribers for the past year; but that no other number for 1871 will be sent to any one unless his subscription for the current year is paid. Intending subscribers should send in their names and remit promptly, as the paper is not now stereotyped, and the number printed will be regulated by the subscription list.

Advertisements for the "Canada Farmer" must be sent in to the office of publication early, and in order to secure their insertion in the forthcoming number, must in no case be later than the 7th of the month.

The Canada Farmer.

TORONTO, CANADA, JAN. 16, 1871.

OUR NEW VOLUME.

Once more we greet our readers on the opening of a new year, and issue the first number of another volume of the CANADA FARMER, under every encouragement to prosecute the work with unabated zeal and energy. We tender hearty thanks to all friends—and their numbers increase—who have in various ways evinced their appreciation of our efforts in the past, and shall study to maintain for the journal the reputation already won.

Our aim and objects have been so often set forth that it is unnecessary to reiterate them. We again solicit the co-operation of Agricultural Societies, and all interested in the progress of Canadian Agriculture, and very cordially invite the communications of farmers on all subjects connected with their calling. The pages of the CANADA FARMER are always open for temperate discussion, and the records of practical experience on matters coming fairly within the scope of an agricultural journal.

In accordance with our usual practice, we send this first number of the volume for 1871 to all subscribers for the past year; but no future number will be sent to any one whose subscription for the current year is not paid. Our readers will please take special note of this intimation. Letters are continually addressed to us from parties who have not paid their subscription, asking why the journal is not sent. This first number is the only one sent in advance of the subscription. The price will continue, as heretofore, $1 per annum, including postage. The terms for clubs and societies will be found in the prospectus which accompanies this issue.

Farm Accounts.

A correspondent, over the signature H. P. W., wishes to have explicit information as to the method of keeping farm accounts. We have repeatedly urged the importance of the subject, and now, in compliance with our correspondent's request, we will give, to the best of our ability, a simple plan of farm accounts, such as can be easily adopted by the least educated of our farmers.

H. P. W. gives as a reason why at least fifty farmers keep no account of their receipts and disbursements, to one who adopts some system for this purpose, that many find they "don't know how." Now, we would supplement his very plain, matter-of-fact reason by another—that they *will not* see the advantage of anything new to them, or of anything approaching to what is generally termed book farming. Many say, what can be the benefit of keeping accounts to me, for I have gone all my life, and not done so badly either, with no attempt at book-keeping? This reason doubtless seems to many as not only feasible but forcible, and yet it may be well answered by the known result of certain parallel platitudes. Many a man has gone for years without a proper provision of clothing, neglecting his body, and defying the rigour of a severe and changeable climate, but in the majority of cases has he not, in his advanced years, earnestly repented of his imprudence?

To those who have never kept accounts, we say, you don't know the advantages to be obtained. Begin at once upon the first day of the new year, and be assured that if you give the attempt a fair trial, you will not relapse into your former ignorance of the state of your affairs and exchequer.

Now, let us give a few instances in which the farmer has done himself much injury by a neglect of some simple system of book-keeping—some tally of his cash and other transactions.

A neighbour ran an account at the blacksmith's shop, and the other day he came in considerable trouble, asserting that the smith had charged him for a great many jobs that he had never had done. What remedy had he? Why, positively none, but an appeal to law, which, with the scant evidence that our friend possessed (his own memory), would in all probability have resulted in an unfavourable verdict, with its accompanying addition of costs. We managed to convince him, sorely against his will, that not only had his whole trouble in this case arisen from a neglect of keeping some simple memorandum book, but that there could be no possible doubt that in his long experience he had both been cheated and had cheated himself over and over again. We showed him the simple system of accounts which will be presently submitted to the reader, and he departed assuring us that he would from that date follow out the advice given.

It is a moral impossibility for a man to retain in his mind a record of all the odd jobs that he has to have done by the blacksmith, the harness maker, the waggon maker, and all those other mechanics and tradesmen with whom he is in business brought in contact. Even allowing, for a moment, that a man should be possessed of such a wonderfully retentive memory as to be able to keep such record in his mind, this power would be found of little value when a bill or a dispute came up for decision in a court of law; there they require black and white evidence on such matters.

Again, at one season a man buys a plough, giving in payment his note of hand; he makes no entry of the transaction, and presently he buys first one thing and then another upon credit. The latter articles are perhaps not absolute necessities; and he would not have gone into debt for them, had he been able, by glancing at his accounts, to perceive how many liabilities he had already incurred.

It may be said against this that a man should do nothing but by cash transaction, and then his only account need be his balance at the bank. The principle is good, but such is not a practical possibility to the general run of Canadian farmers. Until we become, as a class, men of larger capital, the credit system must continue. Moreover, from the very nature of the farmer's business, from the fact that his returns are not quick, but come in at long intervals in large sums, much as we may regret that it must be, yet we cannot now, nor shall we ever be able to adopt the cash system between the farmer and those whom he honours with his custom.

A book might be filled with instances of the losses directly and indirectly resulting from the neglect of book-keeping, and with "awful examples" of men who have sunk deeper and deeper in a mire of debt, simply from the fact that they never did know exactly to what amount they were at any one date liable.

Strictness and accuracy in book-keeping may be arrived at without elaboration or intricacy. If, however, a farmer is able to keep such a close and minute set of books as will enable him at any given time to state the precise cost of each operation in the field, or the exact relative values of different processes of feeding, of different classes of cattle, or of different modes and rotations of cropping, so much the better, not only for the individual, but for the instruction of his brother farmers, and of those who shall come after him.

All that is absolutely necessary is such a current account as will enable a man to find out any day what he owes and is owed, what he has spent in a given time or in a given way, and what he has realized by his sales.

In this money account let him embody his general memoranda, so that he can make this book not only an account book, but also a daily record; this will be the first book, which may be called a *Day Book*.

The second book he may call his *Account Book*, or *Ledger*.

Let us now proceed to briefly illustrate the method of keeping each:—

The following is an imaginary sheet in the Day Book, extending over two pages as you open the book:—

FROM ——— DAY OF ———, 187—, TO ——— DAY OF ———, 187—.

DATE	MEMORANDA.	LEDGER FOLIO.	CASH RECEIVED.	CASH PAID.	TRANSACTIONS NOT CASH.
	ACCOUNTS.		$ c.	$ c.	$ c.
April 1.	40 bushels barley at 80c				
"	Expenses to Toronto with barley			1 50	
"	2 stable pails			60	
"	For 20 bushels seed oats from J. Smith at 60c.			12 00	
Friday, 10	Daisy calved to-day (bull).				
"	4 lambs from 3 ewes.				
"	Engaged John Jones at $15 a month from 21st April				
"	Sold Robinson, 2 tons of hay at $11				21 00
Mon.,	21	Sowed 6 acres barley with 144 bushels.			
"	"	Seeded down same with 20 lbs. clover and 30 lbs. timothy.			
October, Sat.	12	Threshing—Wheat, 220 bushels off 7 acres.			
"	"	Barley, 100 off 4.			
Mon.,	21	Had two horses shod and iron plough fixed at Jacques'		2 50	
Sat.	29.	Put up two hogs to fatten, feeding chopped peas		8 00	
Nov.,		2 steers 3 years old—Hay, turnips, and a little chopped peas			
"		Sold 100 bush. apples to W. Hillman, at 75c.			
"		Sold you 6 cords of wood, to be delivered in six months at 6 per cent			120 00
			$ 22 00	$ 90 00	$ 141 00

And so on.

Now, any farmer can buy a blank book, let it be a good wide one, and rule it himself, as in the above sample; or he can, by paying a little more, have it thus ruled by the bookseller. This ruling extends over both pages of the book opened. The first side is exclusively devoted to important memoranda. The second side has a place for items of *accounts*, a column for any actual cash the farmer receives, and a column for any actual cash he pays out. Notes of hand, either given or taken, produce given to set off against a tradesman's account, or any money matter in which *hard cash* does not actually pass from or to the farmer, should be entered in the third column.

Now, before we leave this account, it may be well to suggest a method by which the farmer can be certain of keeping the money part correct. 1st. *Enter the day's transactions every night before going to bed.* 2nd. Keep a tin box in the house, into which *all* your cash at home should be put. Never put any money in that box without *at once* entering in your day book how you got that money.

Never take any money out of the box without saying in your book what you are going to do with it, except in one case. If you take out a sum, say $15, before you go to town, and you do not know what the price will be of the articles you are going to buy, instead of entering *then* in your book, put back in the box what is called a "due-bill," that is, a piece of paper with $15 written on it. Thus, when you come home, you can open the box, and you will see a paper with $15 written on it, you will then know that you took that sum out of the box. *Before* you take out that paper, be sure and account in your book for the $15 taken out of the box. When the entry is made in your book, you can tear up the paper.

Last and most important, *Never trust to memory* in book-keeping.

The *Account Book* or *Ledger*:—

In this book there will be nothing new. The book is used for the purpose of putting in order, one below the other, every item entered in each column of the day book.

The ordinary merchants' ledger, kept by all booksellers, is the very book required. When you have one, divide the book in two parts. One part will be a cash account, or will be composed of the items in the first two columns of the day book, set upon their proper sides. The other will be a "transactions not cash" account, and will be composed of the items in the third column of the day book, set upon their proper sides. In both cases the account will be, as in the day book, carried on upon the two pages of the opened book.

The following examples show the manner in which the foregoing entries from the Day Book would be transferred to the Ledger:—

CASH RECEIVED.

DATE.		$ c.
April 1.	40 bushels barley at 80	32 00
Oct. 12		

CASH PAID.

DATE.		$ c.
April 1	Expenses to Toronto	1 50
"	2 stable pails	60
"	20 bush. seed oats	12 00
" 21	Robinson, serving cow Daisy	50
Oct. 12	3 men, threshing	3 00
" 21	John Jones, for 6 months' wages	90 00

TRANSACTIONS NOT CASH. RECEIVED.

DATE.		$ c.
April 21	12 lb. butter to go against Jackson's account against me, at 25c	3 00
Nov. 29	Smith's note for value of corn, 6 months at 6 per cent	120 00

TRANSACTIONS NOT CASH. PAID.

DATE.		$ c.
April 21	For plough, gave note to James & Co., for five months, for	21 00

And so on throughout the year.

If you require to balance your book at any time, you simply have to add up the disbursements and the receipts separately, subtract the former from the latter, and the result should be the sum that you have in hand. If you wish to know how much seed has cost during the year, you have only to run your eyes down the *Paid* column, pick out each item of seed and add together, so you can find how much you realized by your barley or your wheat, or your cattle, or any other special produce.

In the account headed, Transactions not Cash, by adding up the column on the left page, the farmer can tell at any time what is due to him, and by adding up that on the right page, knows at once how much his outstanding debts amount to.

There are other more elaborate systems of book-keeping, which might be preferred; but we have given one of the simplest, and endeavoured to make the explanation so clear that any farmer may practise the method.

Agricultural and Arts Association.

ELECTION OF MEMBERS OF COUNCIL.

By the provisions of the existing statute, the annual meetings of all the Agricultural Societies in the Province of Ontario must be held during the third week of January—that is, between the 15th and 21st days of the month, at which meetings accounts will be rendered, and the officers elected for the ensuing year. The Act also provides that four of the members composing the Council of the Agricultural and Arts Association, shall annually retire, and their places be filled by a fresh election from the districts which the retiring members respectively represent. The Secretary of the Association has accordingly issued a circular notifying the names of the members who this year retire in rotation and the districts to which they belong. The circular is addressed to the Secretaries of the Societies immediately concerned, and is as follows:—

SIR,—In accordance with the provisions of the Agricultural and Arts Act, I beg leave to state that the undermentioned members of the Council of the Agricultural and Arts Association of Ontario will retire in the month of January next, viz:

District No. 5.—Durham, Northumberland, Peterboro' and Victoria—John Walton, Esq., Peterborough.

District No. 6.—York, Ontario, Peel, Cardwell, and City of Toronto—Geo. Graham, Esq., Brampton.

District No. 7.—Wellington, Waterloo, Wentworth, Halton, and City of Hamilton—James Cowan, Esq., Galt.

District No. 8.—Lincoln, Welland, Haldimand, Monck and Niagara—J. C. Rykert, Esq., M.P.P., St. Catharines.

The retiring members are in all cases eligible for re-election.

In Section 14 of the Act it is provided that the County Agricultural Societies in the several Districts represented by Members whose term of office has expired, shall, at their annual meetings provided for by Section Thirty-Seven of the Act, each elect one person to represent it at the Council of the Association, by a majority of the votes of the members of the Society present at such meeting; and the Secretary of each Society shall, *within eight days after the election, forward to the Commissioner of Agriculture the name of the person chosen by the Society.*

In section 37 it is provided that the said Societies shall hold their annual meetings in the third week, that is to say, between the fifteenth and twenty-first days inclusive of January in each year.

I beg leave respectfully to request your attention to the above requirements of the Act.

I have the honour to be, Sir,
Your obedient servant,
HUGH C. THOMSON.
Secretary,
Agricultural and Arts Association.

It will be seen that by this elective system, the management of our Provincial Association rests with the Agricultural Societies generally, and virtually with the farmers throughout the land, for every intelligent farmer should be a member of an Agricultural Society. It is too much the fashion in some quarters to cast indiscriminate blame on the Association and the governing board. Instead of so doing, it would be far wiser for every farmer to exercise the power of franchise, and see to it that right men are deputed to represent the interests of agriculture in the Council. With well-appointed officers in our Agricultural Societies, and fit representatives on the Board of the Provincial Association, we are persuaded the present law will in the main work well, and the true interests of agriculture be promoted throughout the country.

Foot and Mouth Disease.

This annoying disease has shown itself among the cattle in the State of New York, and Mr. Harison, Secretary of the New York Agricultural Society, has made a report upon it. After stating the character of the disease and the extent of its depredations, Mr. Harison goes on to say:—

"It appears to be almost certain that the contagion was conveyed to Duchess county by a drover, who, finding on his arrival at Albany with a lot of Canadian cattle that they were sick and unsaleable, and being afraid to go to any large market, shipped the animals to Poughkeepsie, and drove them thence across (by way of Pawling and Dover) to New Milford and Kent, in Connecticut, where the disease, as Dr. Guernsey is informed, is spreading quite extensively. Professor Law found it also in Massachusetts, in the neighbourhood (if I understand him rightly in a hurried interview on the 15th,) of Framingham, and there also the introduction of the disease is attributed to Canadian cattle. Mr. Law recommends the prohibition of the importation of cattle from Canada until the disease shall have been got rid of there; and if this is immediately ordered, and the diseased herds are rigorously secluded and the buildings disinfected properly, we shall probably be out of danger in a few weeks. If, however, we continue importing fresh contagion, there is no knowing where the end will be."

Now, as we do not doubt Mr. Harison really believes that the disease in question went from Canada to the United States, and is honestly trying to check its inroads, it will relieve his anxiety to know that the story is totally without foundation so far as Canada is concerned. There is no foot and mouth disease in Canada—not one case—nor has there ever been an authenticated case of it known

at any time in this Province. Had such a disease appeared in any part of Upper Canada, a week would not have passed before full particulars would have been communicated to the WEEKLY GLOBE or CANADA FARMER; but nothing of the kind, has been hinted at from any quarter. But to remove all doubt as to the non-existence of any case of the kind in Canada, we applied to Dr. Smith, head of the Veterinary College of Ontario, and got from him the following reply:—

"SIR,—My attention has been called to a statement in American papers that the Foot-and Mouth Disease *(Epizootic Aphtha)* has appeared in some parts of the State of New York, and that the disease was introduced into the adjoining State from Canada, where, it is said by the same journals, the malady has been some time prevailing.

"With regard to the existence of the disorder in this country, I have no hesitation in stating my belief that it has been hitherto altogether unknown amongst us, and, as far as my observation goes, the health of stock throughout the Province is excellent, and our cattle are entirely free from any disease of a contagious nature.

"I am, &c.,

"ANDREW SMITH, V. S.

"VETERINARY COLLEGE,
Toronto, Dec. 29, 1870."

We trust, therefore, that Mr. Harison will either withdraw a statement so unjustly injurious to Canadian farmers, or let us know something about that drover. Who is he? What is his name? Where does he live? In what part of Canada did he buy the cattle? From whom did he buy them? and to whom did he sell them? Let us have all the facts, were it for nothing else than the singularity of the whole story. Fancy a herd of cattle, suffering under "foot and mouth disease," gathered together in Canada—carried by rail 500 miles to Albany! There so sick as to be unsaleable; but re-shipped, nevertheless, at Albany to Poughkeepsie, 75 miles farther! Driven on foot from Poughkeepsie to Pawling; thence to Dover; thence to New Milford, and thence to Kent, in the State of Connecticut! And we are to believe that the New York and Connecticut farmers bought this rascally drover's beasts covered with "blisters and ulcers," carrying disease and death into their own barn yards. We submit to Secretary Harison that he really must have that drover hunted up.

Counting acres, taking mortgages, going over stock, and calculating interest, will not answer the question, "How rich is a man?" He is rich or poor according to what he is, not according to what he has.

Knowledge in Agriculture.

Every farmer is, or should be, a *practical chemist*. By this we do not mean that he is to be obliged to go through a course of studies, but his observation of the constant changes going on in the forms of matter, and the results attained by the application of different modes of culture and manuring each crop he grows, as well as the influences of atmosphere and climatic circumstances on the growth of plants, teaches him that there is something of the workings of chemical science mingled in all his undertakings, and according as he can clearly trace and understand the tendency of cause and effect, as he may do by the study of agricultural chemistry, so will he be successful in carrying out his undertaking of making the earth teem with riches Liebig has somewhere said, "there is no profession which can be compared in importance with that of the agricultural, as to it belongs the production of food for man, on it depend the welfare of the human species, the riches of States, and the success of commerce."

We are supposed to know that in all excrements of the live stock kept on a farm there is a substance called *nitrogen*, which by fermentation is converted into a more volatile substance, called *ammonia*, which is invisible, readily escapes into the air, and thus becomes lost, leaving only its salts behind. This substance is the most powerful fertilizer of plants we possess, as no plant can grow up to produce seed without it. There are, however, certain substances for which this ammonia has a greater attraction or affinity than for air, and which therefore can be employed to prevent its escape. These are called fixers of ammonia.

The quantity of ammonia in dung is not absolute, but proportionate, being largest in that of animals that feed exclusively on grain, and larger in proportion in that of the same class of animals, according to the quantity of grain or nitrogenous food they consume. The dung of a horse fed on hay alone is of considerably less value than that of a horse that gets a fair proportion of oats in addition. Cattle fed on grain give a more valuable manure than those that have the run of the straw-yard only.

It is only as the true principles of the nutrition of plants and the nutritive values of different foods of animals and the manures obtained by feeding them become generally known among agriculturists, that they can advance to a proper appreciation of their calling, and discover how much economy can be shown in controlling and managing nature, so as to make the most of her various resources. It is true that in the present time many excellent farmers are apt to look upon such acquired knowledge as unnecessary and superfluous, and rail at it as "book farming;" but they belong to a past generation, and as time goes on and civilization advances, it will be considered a reproach for any intelligent farmer to be ignorant of the leading principles of his profession, as embraced in a knowledge of agricultural chemistry. A very concise, and yet thoroughly practical and suggestive work on this subject, and one that ought to be in the hands of every young farmer, is Prof. S. W. Johnson's recent book, "How Crops Grow."

Beet Root and Beet Root Sugar.

We have been inundated with enquiries on this subject, correspondents asking us for the minutest details, to give which would require the editor and all concerned to be practical sugar manufacturers and sugar refiners, which they do not pretend to be. We furnish for the most part only *general*, and not, in cases like the present, *special* information. Persons who wish to go into the depths of the manufacture must enquire and study, and post themselves fully by the perusal of far more elaborate treatises than can be afforded by newspaper periodicals. We cannot undertake to answer all the separate and private enquiries that are made of us, and of those connected with this paper. Parties must read for themselves, form their own judgment, and act on their own common sense. There is plenty of this latter article among our agricultural readers. The object in view is an important one, namely, the production of a cash crop, which, with ordinary cultivation and good farming, should produce at least forty dollars an acre, where the roots alone are raised. The sugar, when made, will produce about as much more, and the crop of sugar beets will be a crop in addition to ordinary crops now raised. People who will not strive for such a prize as this are not fit to be helped, but in this as in all cases they must bear in mind the maxim that "those whom Providence most helps are they who labour with the greatest assiduity to help themselves."

Our inquirers will therefore please not to expect individual answers to questions put by letter on the foregoing articles. The subject will be continued from time to time, and is by no means exhausted. By waiting for another issue of the paper, the very questions asked may, and most likely will, be answered.

HORACE GREELEY'S ESSAYS, "What I know of Farming," which have been published in the *Tribune* every week during 1870, are to be printed in book form, and a copy will be sent, post-paid, to each subscriber who sends $10 for the Daily, $4 for the Semi-Weekly, or $2 for the Weekly *Tribune*, and requests the book at the time of subscribing. This will enable old subscribers to secure the Essays for preservation, on renewing their subscriptions, and new subscribers will, of course, be glad to obtain them, free of cost.

Agricultural Societies.

That these organizations among farmers have done much to advance the interests of agriculture, and encourage improvement in our system of husbandry, admits of no question. It is a good sign of the times that they are becoming more numerous each year, and that their attempts to awake an interest in the minds of the general public on the subject that so much concerns their well-being, namely, the production of their food and clothing, is meeting with great success. While much has already been done in the way of organizing agricultural societies throughout the country, there still remains much more to accomplish before the good work of improvement may be fairly claimed to be in more than a transitory state.

An article appeared recently in a cotemporary journal on this subject, that contained many good ideas and suggestions, though at the same time it was rather severe on the management of the Provincial Association, and also desired the abolition of the township societies—a measure we are not inclined to favour, at least for the present, or until the new railways now in progress are in working order. That the township societies have been productive of much good cannot be denied. This is especially the case in the more remote townships, and in those counties that have neither railway communication nor good gravel roads running through them. But in some of the older settled and more wealthy counties it is possible that the days of usefulness of the township societies are passing, and that more advantage may be gained by maintaining only the county societies, and endeavouring to make them as attractive and efficient as may be, by giving them such a liberal support from the farmers themselves as will enable them to offer prizes of sufficient magnitude for improved farms, stock and crops to induce men of capital and large ideas to set a good example of what the country is capable of producing.

Another matter that is deserving of attention is the more general introduction of trials of implements at different points. These will necessarily require time and money, and need to be held at a time when materials can be obtained for the implements to be tried upon. As the advantages would, however, rest principally with the implement makers themselves, and the publicity given to their inventions through the reports of the trials given in the columns of the press, rather than from the attendance of the public at the trials, which is rarely large, it would be only fair that they should bear the actual expense, divided *pro rata* among themselves; or by requiring an entrance fee, as is done to some extent in Europe and the United States, the agricultural society under whose auspices it is held furnishing only the prizes and the attendance of judges and proper officers to superintend the proceedings.

Notes on the Weather.

The year just closed has been somewhat remarkable in its meteorological as well as political aspects. It has been the warmest since 1846, the mean temperature being 45° 9, or 1° 8 above the average, every month being above the average except February, March, and November. The excess of the temperature in this locality for each quarter was as follows: Winter, 0° 10; spring, 1° 73; summer 2° 82, and autumn, 2° 67. The highest temperature was 88°4, which occurred on the 18th of June, and the lowest temperature —6°6, on the 21st February, giving a range for the year of 95°. The warmest day, the 28th of June, showed a mean temperature of 77° 7, and the coldest day, 29th of December, a mean temperature of 0° 7.

Rain fell on 116 days, to the amount of 33.898 inches, or 4.374 inches above the average quantity. The heaviest fall on one day occurred on the 11th June, and amounted to 2.360 inches. Snow fell on 77 days, and amounted to 122.9 inches, or 56.8 inches more than the average. This great excess is due to the heavy storms of snow which occurred in the month of March, 62 inches having fallen in that month. The heaviest falls in one day occurred on the 14th January and 27th March, when 16 inches fell on each of these days.

Thunder storms have been frequent and severe. The first occurred in April and the last in November; the most severe occurred on the 11th June. The total number for the year was 34, being the greatest number in one year since 1860.

No special feature, or deviation from the usual character of the month has distinguished the first of the winter months, and the last of the year. The average temperature has been 26° 5, which is, however, 2° 2 colder than December, 1869. The warmest day was the 5th, with a mean of 38° 9; the coldest the 29th, having a mean of 0° 7. This was also the coldest day of the year. The highest temperature occurred on the 5th, 45° 2; the lowest —5° 8, on the 29th.

The quantity of rain was 2.430 inches, being 0.778 inches in excess of the average, and 0.160 inches less than December, 1869. The number of rainy days was six, and the heaviest fall occurred on the 5th, amounting to 1.95 inches. Snow fell on sixteen days, and amounted to 15.9 inches, being 1.8 inches in excess of the average, and 8.8 inches more than fell in December, 1869. The amount of snow throughout the Province has been considerably above that which has fallen in the immediate neighbourhood of Toronto, so that there has been good sleighing generally for the prosecution of winter farm work, as well as for the enjoyment of the pleasures of the season, and—a matter of some importance—there is a fair covering for the winter wheat.

Horticulture.

EDITOR—D. W. BEADLE,
CORRESPONDING MEMBER OF THE ROYAL HORTICULTURAL SOCIETY, ENGLAND.

Report of the Fruit Growers' Association

We continue our extracts from the very interesting and valuable report of 1869, showing what fruits thrive and what enemies the fruit grower must contend with in the counties of Lincoln, Welland, Haldimand, Norfolk, Elgin, Kent, Essex and that part of Oxford and Middlesex lying south of the Great Western Railway.

APPLES.

The replies make it evident that this part of Ontario, extending from the Niagara River and along the north shore of Lake Erie, to Sarnia, having the Great Western Railway as its northern boundary (as near as may be), is the home of the apple in all its varieties. Here the tree, on soil not too wet, thrives in perfect vigour, and the fruit attains its highest perfection.

The following varieties are those most generally named as being profitable market sorts; they are put down in the order of priority of estimation, viz:—R. I. Greening, Baldwin, Spitzenberg, American Golden Russet, Roxbury Russet, Early Harvest, Snow Apple or Fameuse, Northern Spy, Red Astracan, Fall Pippin and Duchess of Oldenburg.

Messrs. Samuel Stoner, A. B. Moore, A. Morse and A. Francis, speak of some varieties as being too tender, naming Cayuga Red-streak, Ladies' Sweeting, Cooper's Market, Ribston Pippin, Hawley, Baldwin, Greening, Spitzenbergh, Northern Spy and Summer Rose. The committee take the liberty to suggest that the apparent want of hardihood complained of, especially in the orchard, may be due not so much to atmospheric changes as to the character of the soil. A cold wet soil is quite uncongenial to the apple, and induces a feeble and sickly condition which causes the tree to suffer from even a moderate degree of cold, and quite naturally the conclusion is drawn that the tree is tender, and the temperature is charged with that which is in reality due to unsuitable soil.

No disease of the tree is named. Insect ravages are numerous enough. The borer, both the saperda and buprestis, the tent caterpillar, the bark-louse, the aphis, the red humped caterpillar and the codlin moth, all contribute to the work of destruction.

Seventeen out of twenty-one name the spring as the best season for planting. A few prefer planting in the fall on light or gravelly soils.

Dwarf trees have been quite generally tried through this division, and the prevalent opinion seems to be that they are more orna-

mental than profitable, except in the case of pears, of which some varieties are very much finer when grown on the quince stock.

PEARS.

The following varieties of pear are evidently the most popular here, and they are put down in the order of preference, viz :—Bartlett, Flemish Beauty, Seckel, Louise Bonne de Jersey, White Doyenne, Vicar of Winkfield, Belle Lucrative, Duchesse d'Angouleme, Tyson, Winter Nelis, Lawrence, Sheldon, Beurre Clairgeau, Doyenne d'Eté, Beurre Bosc, Rostiezer, Beurre Diel, Beurre d'Anjou, Swan's Orange and Brandywine.

Some varieties of pear are spoken of by one or two as tender, but the remarks made by the committee with regard to tender sorts of apple apply with equal force here. It mus be that the tree suffers from some local cause, other than the ordinary fluctuations of temperature.

The following ten varieties, set down in the order of their popularity, are most thought of as market sorts, viz. :—Flemish Beauty, Bartlett, Louise Bonne de Jersey, Duchesse d'Angouleme, Belle Lucrative, Seckel, White Doyenne, Beurre Clairgeau, Lawrence and Beurre d'Anjou.

The burden of testimony is to the effect that there is not sufficient variation within this division to call attention to the varieties as being particularly hardy.

There is not much complaint of diseases or insects. The fire-blight is the only disease of the tree mentioned, and the borer and slug the only insects.

PLUMS.

The following plums are most popular in the order given, viz. :—Yellow Egg, Imperial Gage, Green Gage, Lombard, Smith's Orleans, Yellow Gage, Duane's Purple, Bradshaw, McLaughlin and Coe's Golden Drop.

Plum trees are all sufficiently hardy to thrive in this division.

The following sorts in the order named are esteemed the most profitable, viz. :—Lombard, Yellow Egg, Imperial Gage, Blue Plum, Washington, Green Gage, Prince's Yellow Gage and Smith's Orleans.

Nearly every reply stated that the curculio was very troublesome, often destroying the whole crop.

The black-knot is mentioned by nearly two-thirds of the replies, and some of these complain that it has been very destructive.

CHERRIES.

The following cherries in the order given seem to be the favourite sorts, viz. :—Kentish, Mayduke, Black Tartarian, Black Eagle, Elton, Napoleon Bigarreau, Yellow Spanish, Elkhorn, Governor Wood and Early Purple.

No variety of cherry is really too tender in this section, but the tree will not thrive in wet, cold soils.

The Kentish, Black Tartarian, Mayduke, Black Eagle and Yellow Spanish, are thought to be the most favourable for market.

The tree is remarkably free from diseases or the attacks of insects, but the fruit is often stung by the curculio, and in some seasons rots badly, especially that of the sweet varieties. In damp and heavy soils is apt to "gum."

PEACHES, &c.

The peach tree grows well throughout this division in warm, dry, sandy or gravelly soil. The fruit is often killed by severe cold in the winter or by late spring frosts. The varieties that are most frequently mentioned are the Early and Late Crawford, Early York, Red Cheek Melocoton, Yellow Alberge, Old Mixon Free and Hale's Early.

The quince succeeds well here in well drained clayey soils, and bears good crops of fruit. It is somewhat liable to a blight similar to, if not identical with the fire-blight in the pear, and to the borer. The Orange variety is the one usually cultivated.

Apricots and nectarines require a warm dry soil, and are not very generally grown because of their great liability to be attacked by the curculio.

The strawberry grows well everywhere. The Wilson is almost unanimously designated as the best for market, the one standing next to it is the Triomphe de Gand.

The raspberry thrives well here, though some varieties require to be protected in winter to ensure a crop. They have not been as generally planted as their value deserves. The favourite is the Black Cap, on account of its hardiness. Of the other sorts Brinckle's Orange leads the list in public estimation, both for the garden and market; the Franconia and Philadelphia follow.

Some speak of the English gooseberries as doing very well, but the almost unanimous expression of preference is for Houghton's seedling, on account of its exemption from mildew. The English gooseberries are very subject to mildew, with but very few exceptions, and these arising from peculiarity of soil, the strong clay being best adapted. Downing's seedling is also not very subject to mildew.

But few venture on giving any remedy or preventive of the mildew. Two say that sulphur applied early, by dusting it over the foliage and frequently repeated during the summer, will do much in the way of alleviation; another says leached ashes spread under the plants; another recommends salt and lime applied in the same way; another a thick mulch of long manure, upon which is to be sprinkled thoroughly a weak brine; and another a coating of gravel.

Not much attention given to the cultivation of the blackberry. Some have found the Lawton or New Rochelle to succeed, but more report that it is too tender for the climate. The Kittatinny and Wilson's Early have been planted in a few instances, but it is too soon to speak of their merits.

All varieties of currants thrive well, but the sawfly worm has been very destructive during the past few years, so much so, that in many places the trees have been wholly killed. The favourite sorts are the Cherry Currant, White Grape and Black Naples.

GRAPES.

Every known variety of grape supposed to be suited to this climate, has been planted in these divisions. Nearly every one is sufficiently hardy to endure the climate with the exception of the European sorts, but there are some varieties, such as Allen's Hybrid, Isabella, &c., which are quite subject to mildew, and whenever a vine is badly affected by this parasite, the wood cannot ripen, and is killed by the winter. Indeed, the European sorts would many of them thrive well here, were it not for the mildew. Many vines have been reported to be too tender, merely because they had been ruined by the mildew in summer, and therefore died in winter.

Every variety that ripens its fruit before the Isabella may ordinarily be depended upon to ripen throughout these divisions. There are some localities where the Isabella frequently fails to ripen its fruit, but as a general thing the Isabella will ripen throughout the greater part, and those sorts that are earlier may safely be planted. The favourite sorts at present are evidently the Delaware, Concord, Isabella, Clinton, Hartford Prolific, Diana, Adirondac, Rebecca, Iona, Israella, Croveling, and Rogers Nos. 4 and 15. There are 300 acres of vineyard reported in the County of Kent, planted chiefly with Clinton and Concord. There are several also in the neighbourhood of London, probably of less extent, planted with Concord, Delaware, Hartford Prolific and Clinton, while many other varieties are being tested.

The vine is so far remarkably free from disease. Mildew is spoken of by a few, but most replies state that there is no disease. The only insects mentioned as doing much damage are the thrips and the steel-blue beetle. The former, it is stated, may be very considerably reduced by carrying a torch at night through the vineyard and shaking the vines, when myriads of them will fly into the blaze and be burned.

There is a wide variety of soil and surface within these divisions. Some parts are flat, low and swampy, others rolling, others gently undulating, and few with steep ridges and abrupt hill sides. In the low grounds the soil is quite apt to be heavy, and from the accumulation of water, cold and unsuitable for fruit trees and grape vines, though in the alluvial deposits where there is sufficient drainage to keep the water from becoming stagnant, the raspberry and strawberry will flourish well. But on the rolling grounds, especially those of a limestone character, apple, pear, plum, and grape vine, flourish in great health and vigour, and yield fruit of great beauty, and high flavour. The plum and pear do best where there is

considerable clay, the apple yields its highest flavoured and firmest fruit where there is some clay, while the cherry and peach thrive best in the warmest sandy or gravelly soils. The returns of temperature are very meagre, and of the amount of rain-fall yet more so, hence it is quite impossible to give any average over these counties, but it is believed that the average temperature is much warmer, and the average rain-fall is much less within these limits, than in any other part of Ontario.

Our Best Fruits.

THE RED ASTRACHAN APPLE.

This is our most valuable summer apple. It was brought to England from Sweden in 1816, and from thence it has been scattered abroad throughout the apple region of America. The fruit is exceedingly handsome, the colour being a rich, deep crimson, beautifully heightened by a pale white bloom spread over the surface. In size it is above medium, very smooth and fair, and the flesh is white, crisp and juicy, with a fine, rich, acid flavour. It ripens in the month of August, and may be used as a culinary fruit, but its true place is at the dessert. It sells readily in our markets, taking precedence of every other apple. The tree has proved to be exceedingly hardy, a vigorous grower, bearing young and very abundantly. In all parts of Canada this apple flourishes, and is, if anything, of better flavour in the colder than in the warmer districts, being more juicy and not so liable to become mealy as soon as ripe. It can be safely recommended to every planter as a variety that can hardly fail to give entire satisfaction.

THE DOYENNE D'ETE PEAR.

This is a small fruit, of very good quality, ripening quite early, usually about the end of July. In form it is roundish, slightly pear-shaped; the colour is a deep, rich yellow, frequently shaded with bright red, and covered with gray dots. The flesh is melting and juicy, quite sweet, and of a very pleasant flavour. We esteem it the best of the very early pears that thrive well in this climate. The tree is quite vigorous, bears fruit early and very abundantly, and should have a place in every choice collection.

SUGAR AND ACID IN CATAWBA GRAPE JUICE.—A test was made at Hammondsport, in Steuben county, N.Y., this fall, of the several varieties of grapes grown in that vicinity. Several samples of Catawba grapes were subjected to the test for sugar and acid, and the average of all the samples showed that there were two pounds of sugar in a gallon of juice, and 7 29-100 parts of acid in one thousand parts of juice. That is, the juice stood at about 90 degrees on Oechsle's scale, and the acid was about 7½ per thousandth.

Roses for Canada.

THE PROVENCE ROSE.

Many years ago, when the varieties of roses were much fewer than they now are, there grew in the garden, where many hours of childhood were passed, in playful dalliance with the best roses of the time, one large showy rose, exceedingly double, which was a great favourite with us all. It had been named, by some not very poetic mind, the Cabbage Rose; and now in maturer years, and with much more extended acquaintance with the Queen of Flowers, our riper judgment places the old Cabbage Rose among the very best we have, believing that however brilliant or select may be our collection, it will not be complete without the common Provence or Cabbage Rose. It seems to flourish in a great variety of soils, and to repay a thousandfold any care that may be bestowed upon it. In colour it is a clear rose, perfect in form, and of exquisite fragrance. The half-open buds are as beautiful as heart could wish, and the flowers are produced in great profusion. No one who has enough of love for the rose to care for it will ever regret the purchase of this old, well-tried and ever admired variety—a variety which, after the lapse of half a century, yet retains its place in the catalogues of the best rose-growers of England and America.

Winter Window Gardening.

Use, for this purpose, only such plants as have been prepared for winter blossoming by giving them two or three months' previous rest. It is altogether too much to expect that plants which have been blooming all summer should be covered with flowers in winter also. Give them plenty of room, so that the air and light may have free access. It is a great mistake to crowd them close together. There is more pleasure in a half-dozen well-grown plants than in any number of poor, weakly, drawn-up things. Keep the temperature as uniform as may be, letting it fall as daylight fades, so that the night temperature shall be from fifteen to twenty degrees cooler than during the day. It is very commonly the case that, for a part of the night at least, this is reversed, and by drawing the curtains and stirring the fire the temperature is increased. Plants should rest at night, which they cannot do unless the temperature be decreased. When the weather will admit of it, give the plants fresh air, but never let it blow in directly upon them. To sit in a draught is as bad for plants as for human beings. Dropping the top sash a little way, less or more, according to the warmth of the weather without, is the most convenient method. Keep them clean, removing the dust from the leaves by a gentle shower-bath of tepid water from a fine-rosed watering-pot, and by gathering all the dead leaves and all the insects that appear.

Fairy Rings.

A correspondent sends us the following account of one of these curious circles of greensward, commonly known as "fairy rings," of which he desires an explanation. He remarks that:

"The vulgar belief in England is that they are caused by fairies dancing round the circle Some think they are the consequence of lightning; others say they are produced by ants.

"The lawn is now (Dec. 9, 1870) a faded or yellowish green; the ring or hoop is of a grassy green, several shades darker than the lawn, as if it had been manured. The inner diameter is five and a quarter feet, the width of ring or hoop about eighteen inches. The ground is exposed to the sun on three sides, but sheltered at the north by an oak, which is, however, not over it. No tree has been removed from the spot, but it has been part of the lawn for years. No cows or other animals have been allowed on the lawn. There are no marks of ants. No manure heap was made on the spot, and even had there been one, it would not have left an open spot in the centre. The whole lawn was equally covered with a top dressing last autumn, which was raked off in the spring.

"A gardener could not plant a more perfect circle. They are always about the same size."

The explanation of these curious circles is that they are caused by the presence of certain species of fungi, of which the champignon is an example, whose natural habit is to grow in this manner. That is, the original germ sends out concentric filaments under ground, and the outer ends of these filaments become a bed of fungi, which from their manner of production are arranged in this regular ring. They fertilize the grass, and give to it in that particular circle a peculiar verdure. Our correspondent is mistaken in supposing that they are always of the same size.

The Japan Lilies.

These have been found on trial to endure our winters even better than our native lilies, and to flourish in a greater variety of soils. They surpass all others in beauty, and are most deliciously fragrant.

To grow these beautiful flowers in perfection the ground should be dug fully eighteen inches deep, and enriched with surface soil from the woods that has been well mixed with plenty of coarse sand and old—not less than two years old—well rotted manure. The bulbs should be set five inches below the surface, and remain for several years without being disturbed.

The white Japan Lily is pure white, without any spots, and is very healthy.

The red Japan Lily is really the most beautiful variety, marked with deep red spots, and suffused with a rich roseate hue.

There is a faintly spotted variety, known as *punctatum*, which is very delicately coloured, but the bulbs seem not to possess as healthy a constitution as the other varieties.

We believe the variety known under the name of *roseum* is nothing more nor less than the red Japan Lily, which varies in its shades of colour very considerably, and although often priced higher in the nurserymen's catalogues than the red (*rubrum*), not worth any more in reality. They are now so low in price as to be within the reach of every one, and we hope very soon to see them in every garden in the country.

Bark-splitting.

To the Editor.

SIR,—"Observer's" plan for protecting fruit trees from injury by mice is an excellent one; but as regards the splitting of the bark, I cannot see it in the same light that "Observer" does. He seems to think the splitting is caused by water collecting in a small pool, and freezing around the roots. Allow me to give my views and experience as to the cause :—

After conversing with several of mymost painstaking neighbours on the subject, and carefully examining many trees, I have come to the conclusion that the splitting is caused by hard freezing at night, and the heat of the sun through the middle of the day. In the first place, I ask if any person has had trees injured either on the east, north, or west side, by the splitting of the bark? I find that in nearly every instance the bark is split on the south or south-west, say from twelve to two o'clock, when the sun is at its greatest heat, and takes the frost out of the bark, in a narrow strip up the body of the tree, and the frequent freezing and thawing through the latter part of February and through the month of March, in my opinion, is the cause of the bark splitting. Trees that are inclined to lean to the north are the most in danger, as they have but little top on the south to protect the sun from the body. Trees inclined south, with low bushy tops, are not in much danger. Young, tender trees are more liable to split than older ones. The bark is more tender and glossy, and the sun has more power on them than on older trees. We have one tree in our orchard that met with the misfortune several years ago, of having its bark split up the body, and in several instances the branches, where they lay fair for the sun, had cracks in their bark a foot or more long. I was on the look-out for such things, and noticed it soon after the bark was split, and applied some grafting wax both to the body and branches. The tree is now as sound and thrifty as though nothing had happened to it. The best preventive that I know of is to shade trees most in danger. Say take two strips of board six or eight inches wide, with one straight edge, nail the flat of one to the edge of the other, which will form a half square. Set them up on the south side of the trees, and let them remain until warm weather sets in; then they can be removed and all will be safe. Any other substitute for a shade will answer every purpose.

Tramping or packing the snow down around fruit trees several times through the winter is a great preventive against mice barking trees, especially the outside row, where the snow is apt to drift. Soft damp days are the best, as the snow will pack hard, and the mice cannot work through or under it if properly done. It will also have the tendency to make the trees start later in the spring, and throw the blossoming out of the way of the late frost that is so apt to injure the fruit.

A LOVER OF FRUIT.

December, 1870.

Gen. Grant Tomato.

We have been very much pleased with this variety of tomato, and believe it will give very general satisfaction. It matures its fruit, which is smooth, solid, and fine flavoured, early. A writer in the *Rural New Yorker* says that last spring he sowed some seeds of the General Grant tomato in a hotbed, transplanted them to the open ground in the latter part of May; when they were a foot high he commenced tying them up to stakes six feet high, and after the first blossoms set cut off all the laterals, leaving only the main stem to grow. Then he applied liquid manure, which he obtained by setting up a leach of horse manure. His first ripe tomatoes were gathered the 24th of July, and plenty of them. The vines were covered with beautiful smooth tomatoes, and continued to bear until the frost killed them.

To Prevent Mice from Gnawing Trees.

To the Editor.

SIR,—A good many communications have appeared in your paper, suggesting several ways in which to keep mice from gnawing trees. I will give you my plan :—

I use felt roofing, or such as is put on flat roofs. Take one end of a roll of felt, lay it on a board and draw a knife across it, the width you require to go round the trees; then divide crossways, and you have two pieces, and so on to the amount required. Two or three hundred pieces can be carried in a basket while putting on. One roll will do from four to five hundred trees, according to size, and the same amount can be cut in one hour.

The material is cheap, and durable if taken care of. If the felt is very moist with the tar, tie it loosely round, else it might do injury. It will soon harden, and the strings can be cut away, when the felt will remain if wanted, and loosen with the expansion of the tree, and thus be of service forseveral years. It might also prevent injurious results from insects ascending the trees in summer. In this way I have gone over an orchard of nearly one thousand trees, and when spring comes, I hope to feel satisfied with my labour, as considerable damage was done last winter.

It is not necessary to purchase first-class material; stuff that is somewhat damaged will do quite as well. The greater part of mine cost me nothing, having been taken off an imperfectly laid roof.

J. McL.

Owen Sound, Nov., 1870.

Grape Culture.

To the Editor.

SIR,—I am an amateur grape grower. I have two hundred vines planted, mostly Concord; so far they have been growing wild, but next year they will require pruning and trellising.

Now, I do not want to buy my experience in grape raising as dear as I have in some other things that I have tried—bee keeping for example. I want the experience of others, and will spare no expense to get it, if it is worth having.

Andrew Fuller on the Grape, I believe, is considered the best authority in America. I have his work; and his system of pruning, trellising and training appears to be sensible, practical, and easy, and one that I would like to follow; but I wish to begin right, for whatever system we adopt must be followed up, as if not it will be a loss to the grower.

Some of our Canadian grape growers say, prune and pinch; others say, no, let the vine grow. Some adopt the arbour system of trellis, others approve of the straight trellis; some say, run the wires horizontally; Mr. Fuller says, run them perpendicularly, and I think his reasons are good for doing so.

Now, the question I wish to ask is this: Shall I, as a new beginner, take Mr. Fuller and follow his system right through to the letter, or take my chance, and do as Tom, Dick or Harry advises, or as my own ignorance may dictate? An answer to the above may be interesting to others besides,

A. C. ATTWOOD,
Vanneck P.O.

THE BERBERRY AS A HEDGE PLANT.—The berberry is a pleasing ornamental shrub, and answers well as a fancy hedge or screen; the bright yellow flowers in spring, and the scarlet or purple fruit in fall, which often hangs on nearly or quite all winter, producing a very pretty effect. A deep, rich loam suits it best, but it will grow well in any dry soil.

The Aspen.

Every country place should have that very coquette among trees, the aspen. It seems never to sleep. Its twingling fingers are playing in the air at some arch fantasy almost without pause. If you sit at a window with a book, it will wink, and blink, and beckon, and coax, till you can not help speaking to it. That must be a still day that does not see the aspen quiver. A single leaf will sometimes begin to wag, and not another on the whole tree will move. Sometimes a hidden breath will catch at a lower branch, then shifting, will leave these still, while it shakes the topmost twig. Though the air may move so gently that your cheek does not feel it, this sensitive tree will seem all of a shudder, and turn its leaves upward as with shuddering chill. It is the daintiest fairy of all the trees. I have seen such fair sprites, too, in human form. But one does not get off so easily if he takes too much sport with them. The aspen leaf makes no wounds. Its frolics spin no silken threads which one cannot follow and will not break.—*Henry Ward Beecher.*

Like all things mortal it has its failures and its disappointments, and there are some things hard to understand. But it is never without its rewards, and, perhaps, if there were nothing but successful cultivation, the aggregate enjoyment would be less. It is better for the occasional shadows that come over the scene. The discipline, too, is most salutary. It tries our patience and it tries our faith. But even in the worst of seasons, there is far more to reward and encourage than to dishearten and disappoint. There is no day of the year without something to afford tranquil pleasure to the cultivator of flowers, something on which the mind may rest—rest with profit and delight.—*Cornhill Magazine*

Gardening in the Evening of Life.

I would recommend to every man, especially in the autumn of his life, to take to gardening, if he has not already experienced its pleasures. Of all occupations in the world, it is the one which best combines repose and activity. It is rest in work and work in rest. It is not idleness; it is not stagnation; and yet it is perfect quietude.

The Kilmarnock Willow.

We give our readers an excellent engraving of this very handsome and very popular drooping tree. So perfect is the representation that no description is needed. The tree has been planted in nearly every part of the Province, and we believe it has been quite hardy everywhere. Its graceful, pendant habit makes it a very ornamental tree, when planted around our dwellings. It is grown by grafting it at the desired height upon the black willow stock, from which point the branches grow downwards.

The winter meeting of the Fruit Growers' Association of Ontario will be held in the Court House, in the City of Hamilton, on Tuesday, the seventh of February, 1871, commencing at 10 o'clock, a.m., and continuing throughout the evening.

The Profits of Grape Culture.

We find in *Hearth and Home* an account of the cost of growing and selling the grapes from 2 73-100 acres of vineyard. We condense the account for the benefit of those of our readers who are interested in grape culture. The cultivator puts down the cost of cultivation from the time of gathering the grapes the previous autumn to the commencement of picking them this year at $233 51. This includes cultivating, hoeing and pruning, and 800 pounds of ammoniated superphosphate of lime applied to parts of the vineyard. The cost of picking, packing, and marketing, including freight and commissions and wear and tear of crates, he gives at $227 88, making total cost for the year $461 39. His crop of grapes was 14,500 lbs., for which he received $1,096 76, so that he received $635 37 profits. In this he does not make any charge for rent of land nor taxes, nor for taking the grapes from the vineyard to the railway station. His vineyard contained 2,000 vines in bearing and 250 younger vines. They are mostly Concords, a few, about one-tenth, Delawares, and some Hartford Prolific, Diana, &c. His first Delawares sold at 20c. per pound, his first Concords at 10c., his Delawares falling to 10c. and his Concords to 6c. before the close of the season. He had about 12,000 pounds of Concords and 1,200 pounds of Delawares, the remainder being divided by some eight or nine other sorts. By this it would seem that it cost him about 3 1-5 cents to grow and market a pound of grapes; that the average gross receipts were about

7½ cents per pound, and the net proceeds about 4 1-3 cents per pound; or $232 per acre.

These grapes were marketed in the city of New York. We wish some of our readers who marketed their grapes here would give us the results. We are frequently asked if grape-growing will pay, and only these who have had experience can satisfactorily answer the inquiry.

Keeping Cabbage in Winter.

Three facts need be borne in mind in putting cabbage away for winter, namely:

1. Repeated freezing and thawing will cause them to rot.

2. Excess of moisture or of warmth will also cause them to rot.

3. A dry air, such as is found in most cellars, will abstract too much moisture from the leaves, injure the flavour of the cabbage, causing some of the heads to wilt and the harder heads to waste.

The most convenient way in this climate is to open a furrow in some well drained place, deep enough to receive the heads, place a conple of rails at the bottom so that any surplus water may be readily carried off; place the heads compactly together on the rails, with the roots up, and then cover with soil, ridging it up just enough to cover the roots an inch or so with soil.

Low-headed Standard Pear Trees.

The advantages obtained by heading standard pear trees low are the following:—

Protection to the body of the tree.

Shading the ground and keeping it cool.

Light is admitted into the centre of the tree.

The fruit colours better and grows larger.

The trees come earlier into bearing.

Closer planting can be practised, and thus the trees protect each other.

Pruning and thinning out of fruit can be more conveniently and expeditiously done.

MR. QUINCE ON THE BEURRE D'ANJOU PEAR.—The Beurre D'Anjou is only a moderate growing tree, and with us has done better when planted as a standard. This is the case wherever I have seen this variety growing. It is only when a few trees are wanted for family use in the garden that, on account of its coming sooner into bearing, the dwarf will answer the purpose better than the standard.

GRAFTING LARGE TREES.—In grafting large trees commence at the top, and leave the side branches for another year. The higher branches draw the sap more than the lower branches, and if first grafted the result is more likely to be successful. Never graft all the branches in one season. It is dangerous to the health of the tree to make the leaves so disproportionate to the roots.

Poetry.

The Two Armies.

BY OLIVER WENDELL HOLMES.

As life's unending column pours,
Two marshaled hosts are seen—
Two armies on the trampled shores
That death flows black between.

One marches to the drum-beat's roll,
And wide-mouthed clarion's bray,
And bears upon a crimson scroll,
"Our glory is to slay."

One moves in silence by the stream,
With sad yet watchful eyes;
Calm as the patient planet's gleam,
That walks the clouded skies

Along the front no sabres shine,
No blood-red pennons wave;
Its banner bears the single line,
"Our duty is to save."

For those no deathbed's lingering shades;
At honour's trumpet call,
With knitted brow and lifted blade,
In glory's arms they fall.

For these no clashing falchions bright,
No stirring battle cry;
The bloodless stabber calls by night.
Each answers, "Here am I."

For those the sculptured laureled bust,
The builder's marble piles;
The anthems pealing o'er their dust,
Through long cathedral aisles.

For these the blossom-sprinkled turf
That floods the lonely graves,
When spring rolls in her sea-green surf,
In flowery, foaming waves.

Two paths lead upward from below,
And angels wait above,
Who count each burning life-drop's flow,
Each falling tear of love.

Though from the hero's bleeding breast
Her pulses Freedom drew,
Though the white lilies in her crest
Sprang from the scarlet dew—

While valour's haughty champions wait
Till all their scars are shown,
Love walks unchallenged through the gate,
To sit beside the throne.

Under the Leaves

Oft have I walked these woodland paths
In sadness, not foreknowing
That underneath the withered leaves
The flowers of spring were growing.

To-day the winds have swept away
These wrecks of autumn's splendour;
And here the fair arbutus flowers
Are springing fresh and tender.

O perfect flowers with lips of bloom!
Surpassing in their beauty
The pearly tint of ocean shells,
To teach me faith and duty.

Walk life's dark way, ye seem to say,
In hope and faith, foreknowing
That when man sees but withered leaves,
God sees the fair flowers growing.

Apiary.

Bee-keeping—Review of the Past Season.

It will be remembered that 1869 was one of the poorest seasons we have known in Canada for many years, so much so that during the winter, over half the bees in the country perished for want of stores; hence the spring of 1870 opened with the number of stocks greatly reduced, and many of them in nearly a starving condition. But as 1869 was one of the poorest, so, on the other hand, 1870 has been one of the best honey seasons for several years. The result is, that bee-keepers find their loss made up in numbers and their stocks in fine condition, while nearly all have taken some surplus honey.

There was, however, in many sections, a drawback experienced in the Spring. The dry weather causing the honey harvest to fail, soon after the drones made their appearance, they were in many cases killed off by the workers, though this did not affect the gathering of honey, as drones do not gather honey; yet it retarded swarming, as the rearing of queens will not commence to any considerable extent when such is the case, and swarming is delayed until another set of drones are sure to make their appearance, the queen always laying drone eggs again as soon as the honey harvest improves. In all sections where this was the case, more or less swarms came off too late to gather sufficient stores, except in cases where they were put into hives containing old or empty combs. Fortunately for such swarms, there were a large number of such hives this season, owing to the great loss of bees last winter. It is always to be regretted by every bee-keeper when anything occurs to retard swarming in this country, as there is no little Fall pasturage. In the section of country where I reside we have nothing growing from which bees can gather anything worth mentioning after the end of August. If they hold their own during September we are quite satisfied; but in sections where buckwheat is grown it is different. The amount of honey gathered this season, I believe, is greater than for several years. The amount taken from single stocks far exceeds anything ever before recorded in Canada. This, however, is partly owing to the introduction of the honey extractor, as by using it more honey may be obtained from a stock than would be stored in boxes under the most favourable circumstances. In order to use them, however, bee-keepers must use frame hives, and become accustomed to handling their bees.

The demand for Italian bees is fully equal to any previous year, and the reputation they have gained for being better workers is generally well sustained. Many are Italianizing their entire stock, and will keep no others, while others are satisfied with simply crossing. And it certainly is a great improvement to the stock to cross them with Italians, for the hybrids are fully equal to the pure, as honey gatherers.

The demand for frame hives is gradually on the increase, and several new patterns—new in some features of their construction—have been introduced; and one is led to believe that, ere long, the market will be flooded here, as in the United States, with a "thousand and one" hives, many of which are not worth the expense of making. As a whole, the interest taken in bee-culture has been as fully maintained as in any preceding year, and the prospects are fair, as the Fall has been exceedingly mild, that the season of 1871 will open under very favourable circumstances.

Though we have had some drawbacks in this country not experienced in many of the United States, yet we are holding our own with our American bee-keeping brothers very well; and though we may not as bee-keepers make quite so loud a buzzing, yet we gather about as much honey. True, they have several journals devoted principally to the interests of bee-culture (of which the *American Bee Journal* is prince), and bee-keepers' associations are organized in several of the States; yet, in point of scientific knowledge, we are as a community of bee-keepers not a whit behind them. We have our yearly meetings known as the "Ontario Bee-keepers' Association," which is held at the time and place of the Provincial Fair. Though we have no journal devoted entirely to the interests of bee culture in the Dominion, yet the CANADA FARMER, has an apiary department, and several of our leading agricultural and secular papers devote a column to the interests of bee culture. May we not hope to see the day when Canada shall be *the* "land that flows with milk and honey?"

Brooklin, Ont.

Bee-hives.

To the Editor.

SIR,—In answer to the note by the editor at the end of my article in the November number of the CANADA FARMER, I must say that if the reporter had made proper enquiry as to the use of certain parts of the hive, he would have been able to give a more intelligent description of it.

The wire screen is to "keep the moth out" when you ventilate, the bottom board being withdrawn altogether. A person residing in the township of Clarke did so with the hive in question during the extreme heat of last season, and obtained thirty pounds of surplus honey.

"Clippings" are wax, not dirt. I have never come in contact with a hive so constructed that the frames formed the inner wall, and I experienced no difficulty in obtaining a patent on such a hive.

Though "rejected as inconvenient by most bee-keepers," I can only say that the New Dominion Bee-hive has met with the largest sale of any hive yet offered in Canada the first year of its patent. It obtained a first prize at the Exhibition at Montreal, over the Thomas hive; also in the county of Northumberland.

Superstition among Bee-keepers.

It is strange how tenaciously we cling to old ideas. The teachings of early days—even the sayings of our grandfathers and grandmothers—have become as it were incorporated into our very selves. No matter if ever so superstitious, we cling to them, loth to give them up. Perhaps in nothing do we see more of this than in the common ideas respecting the nature and habits of the honey bee.

So much is this the case that even among bee-keepers of considerable scientific culture, there are still held wrong ideas, detrimental to proper management. Doubtless we have escaped from the dense fog of superstition in which Virgil wrote, when he tells us that after killing a steer, it was left in the sun, until

"The tainted blood, th this close prison pent,
Begins to boil, and through the bones ferment,
Then wondrous to behold, new creatures rise,
A moving mass at first, and short of thighs.
Till shooting out with legs, and imped with wings,
The grubs proceed to bees with pointed stings."

Yet there is much of superstition still clinging to us. Even in far more modern days the ideas so poetically expressed by Virgil were entertained in England by one who was called the "great husbandman of Cornwall, old Mr. Carew of Anthony.' Here are his directions:—"Take a calf, or rather a sturk (steer) of a year old, about the latter end of April; bury it eight or ten days till it begin to putrefy and corrupt; then take it forth of the earth, and opening it, lay it under some hedge or wall, where it may be most subject to the sun, by the heat whereof it will—a great part of it—turn into maggots, which, without any other care, will live upon the remainder of the corruption. After a while, *when they begin to have wings*, the whole putrefied carcass should be carried to a place prepared, where the hives stand ready, to which, being perfumed with honey and sweet herbs, the maggots, after they have received their wings, will resort."—[Bees, their Habits and Treatment, by the Rev. J. G. Wood].

But we need not go back to the days of old Mr. Carew, for even in our own Canada, with all its boasted light and knowledge, and even in our immediate vicinity, not five years since, I heard an old lady remarking that "the drones are bees that have lost their stings and grown fat." There are those, too, among us, who still hold that her majesty the queen bee is a "he," and they continue to proclaim her ladyship a "King," also believing that the drones are females, and lay all the eggs. By the experienced bee-man it will be seen at once, how a bee-keeper holding this long-exploded theory must fail in his management of bees. But among us there are other equally gross errors, such as that drones are required to nurse the brood; that young bees ordinarily elaborate wax, construct the comb, nurse the brood, and do all the internal work of the hive; that a certain class of bees are appointed to attend the queen, constituting the "queen's train;" that only certain bees gather honey; that young bees never gather honey till three weeks old; that another class are appointed as guard, and are relieved in regular order and at regular hours; that old bees do not build comb.

These are all errors—relics of superstition, if I may so speak—and whoever adheres to them is still in the fog. If drones were required to nurse the brood and keep it warm, as is thought by some, how is it that they exist only during the hottest weather, when, frequently, nearly all the bees require to leave the brood in order to reduce the temperature? In early spring, when more heat is required in the hive than is generated by the bees, there are no drones. The truth is that drones are the male bees, and when the swarming season is past, being of no further use, they are destroyed.

That young bees only elaborate wax is another great error. Every worker bee may elaborate wax, construct comb, gather honey, nurse the brood, attend the queen, stand guard, or lie idle, as the case may be. In a perfect colony there are sufficient bees to do all the work required, and some to spare; and apparently when there is anything to do there are bees ready to do it voluntarily. And, when large numbers of bees are lying out idle on the hive, if removed and given a queen they may be made, so to speak, to adapt themselves to the circumstances and go to work, performing all the different kinds of labour in the hive with equal facility with those that were labouring when they were removed.

As soon as we are thoroughly rid of all the false ideas relative to the honey bee, we shall have better management, and bee culture will be more interesting and remunerative.

J. H. THOMAS.

Letter from Texas.

ITALIAN BEES WANTED.

MR. PRINTER:—I hear you print a bee paper, and I want you to send me one to look at, to see if I like it. Cousin Upson was to see us when he came out prospectin', and he told us about a new sort of imported bees, with striped backs and harmless queen stings that never hurts nobody, and can be handled, like well-riddled rye, without gloves, in the

hottest weather. Mr. Printer, can't you put me in the way of getting a swarm? I would like to have them soon. Can't they be sent by telegraph, so as to come before Christmas? Swarming time begins here soon after New Year, when the drones have got over their holiday frolics. How much will they cost, though? If they are very dear I could not afford the expense till after the next cotton crop is made. They say a queen sells for five or six dollars! Just think of that! A little insect about an inch long selling at the price of a yearling colt! If the workers sell in proportion, won't they come high, as cousin Zeke reckons it out? Or if you put them down at even a picayune apiece, and there are thirty thousand in a hive, only think what a decent hive would come to, by the rule of three! Then there's the freight too, if they come by telegraph, for the ticking clerk always figures that out high; and so I am afraid that, if sent by that line, they might in the end cost more than they would come to. Aunt Dinah says she has read somewhere in the *Penny Whistle Weekly*, (which she gets every now and then at the grocer's around some articles she buys,) that they now send these bees, or some kind of bees, by mail. That, I think, must be a good joke! Why, you might as well send a basketful of hornets by express. Phew, I'd like to stand at a safe distance away and see our soberfaced, steady old postmaster open the bag when they arrived! Wouldn't he make tracks in a hurry, and feel worser nor if he had a dozen big fleas in his ear? No, no, that's a little too tough a yarn to be swallowed by any but a greenhorn, though it is in print. But have those bees I will, sooner or later; and if they don't come quite as dear as cousin Zeke reckons it out, I'll get you, Mr. Printer, to have 'em sent by rail and steam even if they don't come till after Christmas. I'd have them sent by express, but that moves as slow in these parts as our old ox team used to do in old Middlesex, on Saturday nights, when we had hitched up to go sparking. Don't forget to tell the man who sells and sends them, to be sure to give them food enough for such a long jaunt, as the poor things mustn't be let starve on the way. Tell him, too, to pack them well and hurry them forward—"*with speed and care, right side up!*".

Before I close, Mr. Printer, I want to say further, that when cousin Upson was here he told us there was great fuss just now away up in the old States, about some wonderful improvements in bee-keeping, which he said they call "scientific beeculture." Now what is that? How is it made? How big is it? Is it patented? Does it go by machinery? Is it hard to learn how to work it? Or must you go to a sort of school or college to study how to manage it, till you get the hang of it gradually? Couldn't an old man learn to fix it up, without leaving home?

MILES HADAWAY, 3d.

Household.

Packing Pork.

We condense the following directions on this subject from the *Utica Herald*. To prevent meat spoiling in the process of curing, it is absolutely necessary that it should not be allowed to *freeze* before salting. Pig killing is often done in very cold weather, when the meat quickly freezes on the outside, before all the animal heat has escaped from the thicker and deeper portions of the body. Such meat is very apt to become tainted. This matter being first attended to and the carcass taken under cover before it has frozen, it is next cut into convenient pieces for packing.

The barral must, of course, be perfectly sweet, and so strong that there will be no danger of leakage. This being insured, begin the packing, by covering the bottom of the cask with an inch and a half of coarse salt. This is to keep the pork from coming in contact with the cask, and thus being exposed to the air and the almost certainty of tainting. Then put in the layers of pork, one upon the other, and between the layers a heavy sprinkling of fine salt. Cover the last layer with one-half inch of solar salt. Let the barrel stand in this condition three or four days, so that the salt shall work into the meat, and form a sort of brine with the water of the meat itself. Afterwards pour on brine enough to just cover the meat, but not to cover the top layer of salt. Pork packed in this way will keep always.

When the pork is being used, the brine should be dipped out as the pork lowers in the barrel, *so that a layer of salt may be on top.* If the brine is allowed to cover the salt, it will have particles of animal matter floating upon it which, by thus coming in contact with the air, will become tainted, and will communicate this taint to the body of the pork below by means of the brine. A great deal of pork is lost in this way which could have been saved sweet and good if the brine had only been lowered with the pork. None but the best kinds of salt should be used. They will cost but a trifle more, and are often the means of saving an entire barrel of pork.

Domestic Recipes

CHRISTMAS OR NEW YEAR'S CAKE.—Five pounds flour, (prepared,) three and a half of granulated sugar, three of good butter, one dozen eggs, half a pint of wine, half a pint of brandy, one ounce of nutmegs, one ounce each of cinnamon, cloves and mace, one pound of candied citron, two of currants, two of stoned raisins, half a pint of yeast. Make a sponge of the yeast, and set it in the middle of the flour, cover it and let it rise; when risen, add all the other ingredients—previously working the butter and sugar to a cream—bake in one large shallow pan after raising a second time, and when done frost, and trim it with a holly wreath.

COTTAGE PLUM PUDDING.—A pound and a half of flour, four or five eggs, and a pinch of salt, a little nutmeg, one pound of raisins, half a pound of currants, sugar to taste and a little milk. Make a thick batter with five well beaten eggs, a pound and a half of flour, and a sufficient quantity of milk. Then add the currants, washed and picked, the raisins stoned, a little nutmeg, and sugar to taste. Mix all well together, and boil it in a basin or floured cloth for quite five hours. The peel of a lemon grated, and a few pieces of citron out thin may be added.

BAKED SOUP.—Take one pound of lean beef, chop rather fine, place in an earthen pot which will hold five quarts of liquid.—Slice and add two onions, two carrots, two tablespoons of rice well washed, a pint of whole or split peas, a teaspoon of black pepper, and a tablespoon of salt; pour over all one gallon of cold water; put the lid of the jar on it, or a close fitting plate, and bake four hours. This is a nice, wholesome dish.

TO KEEP STOVES BRIGHT.—Make a weak alum water, and mix your British lustre with it; put two spoonsful to a gill of alum water; let the stove be cold, and brush it with the mixture, then take a dry brush and lustre, and rub the stave till it is dry. Should any part of the polish become dry as to look gray, moisten it with a wet brush, and proceed as before. By two applications a year, it can be kept as bright as a coach body.

APPLE SNOW.—Put twelve good tart apples in cold water, and set them over the fire; when soft, drain the water, strip the skins off the apples, core them, and lay them in a deep dish. Beat the whites of twelve eggs to a stiff froth; put half a pound of finely powdered white sugar to the apples; beat them to a stiff froth, and add the beaten eggs. Beat the whole to a stiff snow; then turn into a desert dish.

ROAST GOOSE.—The *Hearth and Home* says a goose less than a year old can be cooked so as to taste almost as well as turkey. When the animal is nearly ready to be killed, put vinegar into its food, and the day before its neck is brought to the block, pour a spoonful of vinegar down its throat. It has the effect—the reason of which is not well understood—of making the flesh tender. Boil slowly for about two hours, if the goose is old, taking care to skim away the oil. One hour for a young goose. Then stuff, and roast, or bake, like a turkey, using a little good vinegar with the basting.

CHRISTMAS PLUM PUDDING.—One pound and a half of raisins, half a pound of currants, three quarters of a pound of bread crumbs, half a pound of flour, three quarters of a pound of beef suet, nine eggs, one wineglassful of brandy, half a pound or citron and orange peel, half a nutmeg, and a little ground ginger. Chop the suet as fine as possible, and mix it with the breadcrumbs and flour, add the currants washed and dried, the citron and orange peel cut into thin slices, and the raisins stoned and divided. Mix it all well together with the grated nutmeg and ginger, then stir in nine eggs well beaten, and the brandy, and again mix it thoroughly together that every ingredient may be moistened; put it into a buttered mould, tie it over tightly, and boil it for six hours. This pudding may be made a week before using, boiled in a cloth, and hung up in a dry place, and when required put into a saucepan of boiling water and boiled for two hours or two hours and a half, then turned out and served with sauce as above.

To Cook Vegetables.

It is often observed that a meal from vegetables is not satisfying. I have found it frequently happen that the persons who thus objected, did not know even how to boil a vegetable. The rule is simple, and should never be forgotten. Every kind of vegetable intended to be served whole should, when put to boil, be placed at once in boiling water; and this applies especially to potatoes and vegetables from which the outer cover has been removed. Now it often happens that potatoes, etc., are, to save time, placed in cold water and left to boil gradually. It is just this which allows the nutritious matter to escape and renders the meal unsatisfying. When, on the contrary, the water boils from the moment the vegetable is immersed in it, the albumen is partially coagulated near the surface, and serves to retain the virtue of the vegetable. The reverse is, of course, the rule for making soup, or any dish from which the water will not be drained. By placing the vegetables in cold water the albumen is slowly dissolved, and actually mixes with the water—a process most necessary for the production of nutritious soup.

A Home-Made Earth Closet.

J. B. Lyman, agricultural editor of the N. Y. *Tribune*, tells how he made an earth closet:

I built a house lately, and managed matters in this way: I bought two camp kettles, sheet iron cylinders with a bottom and a bail; they cost a dollar each, and measure perhaps 14 inches across the top. The seat has hinges, and the kettles stand on masonry, so the seat when down touches the rims. The bail is long enough to fall over the rim, and touches the side half-way down. The shell of a box-turtle serves as a scoop. Once a week the box is filled with dry garden earth or with fine clay; once a week it is necessary to lift the seat and take out the kettles and add the contents to the manure pile, a chore at consumes five minutes. Before the ket-th tles were used they received a thorough coat of coal tar thickened with slate-flour.

We like the system very much. It allows a closet to stand where with any of the old methods it would breed disease. It is cheap and simple; it eaves all the night soil; we have no smell, for if any is perceived, two shovels of earth will quench it. It makes a light weekly chore of what would otherwise become an odious semi-annual job. In the hottest weather we scatter a little quicklime or lime with carbolic acid. Lime alone will quench the ill odor of the fluids of sewage, and the dry earth muffles the other. In freezing weather sifted coal ash is a convenient substitute for soil. Any earth that is not sandy will answer; but it should be dry.

Agricultural Intelligence.

Agricultural Association.

The Council of the Provincial Agricultural and Arts Association met on the 8th Dec. in the Agricultural Hall. The following gentlemen were present:—Hon. D. Christie, President; Hon. James Skead; Messrs. James Young, M.P., Rykert, M.P.P., Cowan, Graham, Macdonald, White, Shipley, Gibbons, Wilson, Walton, Farley; Rev. Mr. Burnett, and Prof. Buckland.

Mr. Young brought up the question of examining the public accounts before they were adopted, and on the motion of Hon. James Skead, seconded by Mr. White, they were referred to a special committee, consisting of Messrs. Burnett, Macdonald, and Cowan. A number of communications respecting the award of prizes were taken up and disposed of. The Council having at a previous meeting decided upon publishing a volume of transactions covering the last seven years, the secretary was instructed to advertise for tenders for the printing of the volume, and a committee, consisting of Messrs. Rykert, Young, and the President, appointed to supervise the publication. The printing of diplomas was referred to the same committee. A communication was received from the President of the Young Men's Association, asking if the Council would sell the Agricultural Hall; if so, for how much? On motion, it was decided to reply that the hall was not in the market.

IRREGULAR VOTING.

Hon. Mr. SKEAD presented a report from the committee appointed at a previous meeting to inquire into alleged irregular voting at the general meeting of the Association. The ollowing is the report:—

To the Council of the Agricultural and Arts Association:

The Committee appointed under the resolution of the 8th of October last, to investigate and report upon the circumstances attending the vote taken at the meeting of the Directors of the Association on the 6th Oct., in reference to the appointment of a place for holding the next exhibition of the Association, beg leave to report—

That having carefully examined the minutes of the meeting of the Directors on the occasion in question, as recorded by your Secretary, and availed itself of all the means of information within its reach, they find that there were in all 128 votes recorded. Of these, several were by individuals who voted as delegates or appointees of different societies, and claiming to vote as such in the absence of their President or Vice-President, but exhibited no satisfactory evidence of such appointment. That several individuals of such alleged appointees assumed to vote without the authority of the society which they pretended to represent. That several of the votes so given and recorded were spurious, and given by parties not legally qualified to vote as Directors of the Association, and therefore that the result obtained by the voting as aforesaid, was not a lawful and just decision of the question then submitted. That your Committee, with the view of giving additional perspicuity to this report, annex hereto and embody herewith a schedule, exhibiting in detail a statement of the votes recorded and the particular facts as found by your Committee affecting their validity. That your Committee would respectfully urge upon the Council the expediency of passing a by-law regulating the voting upon similar occasions, and prescribing the precise form of credentials which a voter shall be required to produce before recording his vote, so as to ensure more regularity in these particulars for the future. Your Committee further respectfully suggest that your Secretary be admonished to keep the books containing the minutes of the different meetings of the Association with scrupulous exactitude, and that he is to be held responsible that the same are not tampered with or defaced. That your Committee, adverting to the schedule appended hereto, would draw the attention of the Council to the fact of there being forty-two votes recorded at the said meeting as having been given by parties who have produced no credentials whatever of qualification, the Committee in consequence having no ready means of estimating the validity of such votes; and it is further noticed by your Committee that even in those cases where credentials have been produced by the voters, such credentials for the most part afford no evidence of the parties therein named having been appointed as delegates by their respective societies according to the Statute—such credentials only going to show that the parties therein named had been nominated or appointed by particular members or office-holders of their respective societies. Also in reference to certain Horticultural and Mechanics' Institute Societies, represented at the said meeting, your Committee are uninformed as to whether the requisite formalities have been complied with in order to entitle them to such representation and report in the premises, assuming all such societies to have been legally constituted.

All of which is respectfully submitted.

J. SKEAD, Chairman.
S. WHITE,
JOHN WALTON,
ANDREW WILSON,
JAMES J. FARLEY.

Mr. EYKERT said the Act did not provide that presidents or vice-presidents must bring certificates.

Prof. BUCKLAND remarked that a blank circular would be sent this year to all the associations for the purpose of securing a list of their officers.

Mr. MACDONALD thought that according to

the Act the delegates should be required to bring certificates

Mr. RYKERT suggested that the Department of Agriculture be requested to furnish the Council with a list of the officers of the branch associations.

Hon. Mr. SKEAD pointed out a number of irregularities and illegalities in many of the credentials that had been sent in previous to the annual meeting of directors. He alleged that the list of delegates had been tampered with, as he had carefully examined it at five o'clock on the evening of the day of the annual meeting, and found only 91 votes on it, and yet no less than 128 votes were recorded when the vote was taken.

Mr. RYKERT contended that the Council had no legal right to pass a by-law regulating the voting at the meetings of the Association. That matter belonged to the Association. However, to bring the matter properly before them he would move the adoption of the report.

Mr. MACDONALD seconded the motion. Considerable discussion followed. It was unanimously conceded that some more stringent regulations respecting the manner of voting were needed, but it was held that that was a matter for a meeting of the whole Association.

Mr. RYKERT withdrew his motion, and the committee agreed to amend that clause of their report by striking out the reference to the passing of a by-law and recommending that some steps be taken to regulate the voting at the annual meetings, and that a precise form of credentials be prescribed for voters.

The report was then adopted.

Mr. RYKERT moved, seconded by Mr. Young, that the Secretary be instructed to apply to the Minister of Agriculture for a list of the officers of the branch associations, and that he be further instructed to write to the several agricultural societies requesting that all delegates to the annual meeting be furnished with proper credentials, at the same time furnishing them with blank forms. Carried.

The Council then adjourned till four o'clock.

The Council re-assembled at 4 o'clock.

The SECRETARY read a communication from Mr. Weld, asking the Council to petition the Legislature for assistance to enable him to carry out his emporium plan, or to accommodate him for the same purpose. The Council decided that, while appreciating Mr. Weld's exertions, they did not feel themselves at liberty to advise the Legislature in the matter.

In answer to the President,

Mr. GRAHAM, the Treasurer, said the Denison case was not yet decided by the Courts.

The Committee on Accounts reported, recommending the payment of a number of accounts amounting altogether to $2,043 60. Other accounts from newspapers for advertisements not ordered were referred to the Council. On motion it was resolved not to pay those accounts.

The report of the Committee was adopted.

The TREASURER, Mr. Graham, presented the following abstract of accounts up to 1st December:—

Balance on hand 1st Jan., 1870...		$1,649 97
Receipts since that date—		
Miscellaneous Accounts.....		771 54
Prize Account.....		112 00
Rents.....		1,000 00
Government Grant.....		10,000 00
Exhibition Receipts—		
Secy. on account of subscriptions.....	$900 00	
Do. on account of booths	1,510 00	
Entrance Fees at Gates	17,454 81	
Forage sold.....	464 65	
Other Items.....	52 00	20,381 46
On account of Denison.....		250 00
		$34,164 97
Payments—		
Miscellaneous Accounts.....		$1,905 09
Prizes.....		11,594 11
Council Expenses.....		1,206 75
Veterinary School.....		550 00
Salaries.....		1,689 98
Printing and Stationery.....		895 84
Legal Expenses.....		410 72
Exhibition Expenses.....		6,944 55
		$25,196 95
Balance on hand 1st Dec., 1870...		$ 8,968 02

Mr. GRAHAM added that there was about $500 yet to come in on Exhibition account. The total receipts were over $3,000 more than those of last year at London.

The PRESIDENT congratulated the Council upon the great success of the Exhibition, and expressed his belief that, all things considered, it was unequalled by any other similar association.

Prof. BUCKLAND presented a statement of expense of outs to illustrate the report of the Entomological Society, $106,77, which was ordered to be paid.

In answer to Mr. Young, the Secretary said there were nearly as many entries in the Stock Register as were in the first Herd book. It was agreed to instruct the Secretary to call for entries up to the 1st of June next for a second Herd Book.

The Council then adjourned.

Birmingham Cattle and Poultry Show.

The Birmingham and Midland Counties Show took place during the last week of November. The entries in all the classes were numerous; but, with some few exceptions, the individual excellence of the animals, says the *Mark Lane Express*, was scarcely up to the high standard one looks for at such an exhibition.

The first prize in the Shorthorn class was won by Mr. Pulver, of Kettering, beating the Earl of Aylesford, who gained the highest honours at the Smithfield Club Show of 1869. The Herefords, we are told, were not as good as usual. Mr. P. Turner, of Leen, obtained the first prize for the best steer, and Her Majesty the Queen the third. The Queen also obtained the first prize for the best Hereford Heifer. The Devons were remarkably good, and as usual of very even excellence.

In the polled class Mr. McCombie, of Tillefour, was beaten by Mr. Heath Harris, of Earnshill, near Forres, Morayshire, though he showed the brother of the famous Black Prince, that carried all before him at Smithfield and Birmingham in 1869. The present steer, shown by Mr. McCombie, is equally fat with his celebrated predecessor, and of exactly the same girth—9 feet 10 inches—but has little beyond his size to recommend him, and rightly gave place in the prize list to Mr. Harris' well proportioned and finely built ox. Mr. McCombie was deservedly successful in winning the first prize for the best cow of the same breed, which has so long been a specialty with him.

In the sheep classes, Lord Walsingham's Southdowns and Lord Berners' Leicesters, as usual, carried off the honours.

The show of pigs was better than usual in all except the class of large breeding pigs. The best fat pig, which the *Mark Lane Express*, our authority throughout in this report, pronounces almost "perfect," was exhibited by Mr. Duckering, of Northope, Lincolnshire.

Mr. R. Fowler, of Aylesbury, was winner in the class of Berkshires. The whole of this class was so meritorious that the judges nearly came to the conclusion of commending all the pens. Her Majesty obtained prizes for some excellent pigs of the Windsor (Suffolk) breed.

Guelph Fat Cattle Show.

The annual Christmas show of fat stock, under the auspices of the South Wellington Agricultural Society, took place at Guelph on Tuesday, Dec. 13, and notwithstanding the unfavourable state of the roads, was numerously attended. There was altogether a fine show of animals, in quality no way behind the excellence which has earned for the farmers of Wellington the highest reputation. The comparative absence of American buyers influenced the sales, but notwithstanding this drawback, some very high rates were paid for choice stock. The prices ranged from $3 50 to $10 per 100 lbs live weight. For fair, ordinary cattle, the figures would run from $3 50 to $4 50; for good, prime beef from $4 50 to $6; and for extra from $6 to $10, and in one case—that of Mr. Telfer's heifer—to $12. But all above $6 may be called fancy prices for fancy animals, and afford no criterion for the average rates paid for the common class of fairly fed cattle.

Some of the cattle had attained great weights. Among some of the most noticeable were Mr. P. Rennie's Sweepstakes prize steer, 2,273 lbs., sold to G. Hood at 11c. per lb. W. Armstrong also sold his cattle, which took prizes at Fergus, to Geo. Hood; one of the steers weighed 2,660, another 2,240 lbs. The two cows weighed 1,940 lbs. each. He sold them at $10 per 100 lbs., and one at $6 25 per 100 lbs. Mr. Hood was the winner of the chief prizes in the class of oxen over four years old, particularly, outstripping all competitors. In the class of cows over four years, seven fine massive animals were shown. The splendid cow owned by Mr. Alex. Watt, of Pilkington, which took the second prize at the Provincial Exhibition, carried off the highest honours. In the class of heifers also, of which there were six exhibited, the one owned by Mr. Watt, which took the first prize at the Provincial Show, carried off the red ribbon. Mr. Telfer was awarded the second prize for a very superior animal, of fine symmetry, which he sold for $12 per 100 lbs. In the sweepstakes a very handsome heifer, in the finest condition, which was fed by Mr. Peter Rennie, of Garafraxa, and sold to Mr. Geo. Hood, took the prize. There was a large and highly creditable show of sheep in all the classes. Messrs. Wright, Millar, Cowan, Walters and Hood were the principal prize takers. There was a fine lot of fat hogs. The turkeys, geese, &c., were both in size and fatness fully up to those shown in former years, and they were speedily bought up at high prices.

Smithfield Club Cattle Show.

The Smithfield Club Cattle Show took place in the Agricultural Hall, Islington, during the first week of December, and excited the usual interest, bringing together some of the finest specimens of live stock, and attracting a large concourse of visitors. Amongst the exhibitors were not only those who make stock-raising their regular calling, but amateurs from the ranks of the noble and wealthy, with Her Majesty and the Prince of Wales among the number, who thus give evidence of the estimation in which they hold the farmers' vocation.

The show this year was, by all accounts, up to the high standard of these annual exhibitions, and following so close on that at Birmingham possessed many of the same features of interest. The principal winners at the Midlands show were also successful in the metropolis, though, as usual, some of the awards at the first were not sustained in the larger competition of the Smithfield show. The show of short-horns was, perhaps, not of extra merit; but that of Devons was particularly fine. The Herefords were good. The champion plate, value £100, for the best beast in the show, was awarded to Mr. Pulver of Kettering, for a magnificent short-horn ox, winner at Birmingham. The gold medal for the best male animal, was won by Mr. Taylor for a Devon. The medal for the best cow or heifer, was also won for a Devon, by Mr. T. L. Senior. Mr. Heath Harris was again successful in the class of Scotch polled steers against Mr. McCombie.

The show of sheep was excellent, headed by Lord Berners' Leicesters, and Lord Walsingham's Southdowns.

The pigs were as usual a splendid lot.

A display of implements by the chief manufacturers in Britain, gave additional interest to the occasion; and the show of mammoth roots was really "prodigious" with mangolds weighing 50 lbs., and samples from crops yielding 72 tons per acre.

MONTHLY CATTLE FAIRS.

ELMIRA.—Second Monday in every month.
LISTOWEL.—The next cattle market will be held on Friday, April 8th, and thereafter on the first Friday before the Waterloo fair.
WATERLOO.—Second Tuesday in every month.
GALT.—Wednesday after the second Tuesday.
AYR.—The third Tuesday of the month.
PARIS.—The Wednesday after Ayr.
TEVIOTDALE.—The Friday before Guelph.
HARRISTON.—Friday before the Guelph fair
BOSWORTH.—Saturday before Guelph.
DRAYTON.—The day before Elora.
ELORA.—The day before Guelph.
GUELPH.—First Wednesday in each month.
NEW HAMBURGH.—First Tuesday in each month.
MOUNT FOREST.—Third Wednesday in each month
DURHAM.—Tuesday preceding the above.
FERGUS.—Thursday following Mount Forest.
ORANGEVILLE.—Second Thursday in January, March, May, July, September and November.
MONO MILLS.—Third Wednesday in January, April, July and October.
ERIN.—First Monday in January, April, July and October.
MASONVILLE.—First Tuesday in February, May, August and November.
BRAMPTON.—First Thursday in every month.

Hon. Horatio Seymour, of New York, is President of a cheese factory, which he considers to be more useful than had he been elected President of the United States.

The decrease in cultivated acres of wheat in Great Britain, according to the returns of 1870, is 5.3 per cent. Barley shows an increase of 5.2 per cent; cattle have increased 1.5 per cent., and sheep have decreased 4.40 per cent. The English evidently know where the money lies in farming.

The import of beet root sugar into England from the Continent is far more considerable than is generally supposed, and has averaged during the last three years something like 50,000 tons—an amount equal to that which she draws from the Mauritius.

The Conestago fat cattle fair was a success. There were present on the ground nearly 200 head and twelve buyers, several of whom were from Toronto, Guelph and Buffalo. Very large prices were in some instances realised, $80 and $90 being a common price for a fat ox.

There are 65,000 acres devoted to hops in England according to late estimates. In 1859 the acreage had fallen to 43,729, but there has been a gradual increase since that year until the present time. Of the total area, the county of Kent has about 33,000 acres, and Sussex 14,500.

The tenth volume of the American Shorthorn Herd Book is now in press. The ninth volume was issued in February last, yet this contains the pedigrees of about 1,800 bulls and 2,500 cows. The volume will probably be ready for the public in February next.

A short time ago a farmer near Decorah, Iowa, lost twelve head of cattle. Eleven died inside of six hours, and all within a radius of ten or fifteen rods of each other. The first impression was that they must have been poisoned. Others have lost cattle in a similar manner; and it is now attributed to eating smut in corn, for the animals had been running in the cornfields for ten or twelve days.

A movement is on foot at Elora for the establishment of a beet sugar manufactory. Several meetings have been held, and the conviction is that the soil of that section of Wellington is favourable to the growth of the sugar beet root. An establishment is also being formed in the adjoining county of Waterloo.

The sale of Mr. Spears' Shorthorns at Tallula, Illinois, advertised in our columns, we learn from the *Prairie Farmer* was well attended and successful. There were 23 head sold. Two brought $1,000 each, and 11, in all, $500 or more each. The lowest price was $150; and the next lowest $225. There were sold at the same time 72 Berkshire pigs at an average of $27 each. A number of the sows sold brought from $50 to $100 each.

The Acclimatization Society of New Zealand have sent to England their agent, to procure for that colony a number of English birds, including 100 sparrows, 100 robins, 100 chaffinches, 100 yellowhammers, 60 goldfinches, 60 linnets, 60 redpoles, 100 blackbirds, 85 thrushes, 120 larks, 2 pairs of blackcaps, 36 English partridges, and 2 brace of bladegame. He also takes out 18 head of red deer.

The *South Land* says that the damage done to the Cuban sugar crop alone, by the recent hurricanes, will have an effect reaching to every consumer of that commodity. The four districts that were devastated by the storm produced 316,000 tons of sugar in 1860, and their production for the present season was estimated at 400,000 tons. As these districts are in a narrow section of the island, it is feared that their entire crop has been destroyed, which will not only tend to raise the price of sugar, but will diminish Spain's revenue from Cuba.

The New England *Homestead* says that the Massachusetts Society for promoting Agriculture has awarded to Major Ben. Perley Poore, of Indian Hill Farm, near Newburyport, the premium of $1,000 which it offered in 1858 for the best plantation of forest trees, planted before 1860 and growing in 1870. The premium was offered in compliance with a statute "for the raising and preservation of oak and other forest trees best adapted to perpetuate, within the State an adequate supply of ship timber."

Mr. Charles Delamere, of New Orleans has discovered a process by which the saccharine property from sweet potatoes can be extracted and its precipitate made into sugar. He took one bushel of potatoes weighing fifty-two pounds, and, with a rude apparatus for extracting the juice, aided by the addition of some ingredients known only to himself, made two and three-quarters gallons of beautiful golden syrup. He estimates that a barrel of potatoes, worth on the plantation one dollar, will yield eight gallons of syrup, which would be sold cheaper than cane syrup.

Miscellaneous.

Backwoods Life

DEER-HUNTING EXTRAORDINARY.

On the morning following the bear-hunting extraordinary already related, I resumed my journey, and the valuation in which I had previously been engaged. A few miles from the scene of the former exploit I came suddenly to another little homestead, cut out of the dense woods. The clearing might be about five acres, and had been cleared the previous spring, and at that time had been partly planted with potatoes and the remainder sown with turnips.

As I cantered my horse through the wood along the pathway, I heard loud calls for assistance, and a female name, and an axe or pitchfork was loudly demanded. I hastened on, galloping my horse round the little field, towards the sound. The trees obstructed me somewhat, but I arrived in time to witness the death of a fine doe in the most extraordinary manner.

It seemed that a doe and her fawn had leaped over a low part of a remarkably well staked and ridered fence. This portion had been lowered as a gap. They were disturbed by the woman of the house returning with the cow through the woods, intending to enter by the same gap. The doe and her fawn ran across the clearing, seeking for some place of exit. It is well known that a doe will not readily leave her fawn within an enclosure if it is too high for the little one to jump over, and the mother therefore ran round the field seeking for some place of egress, but found none. The fence was everywhere ten rails high, double-ridered and staked. After making the circuit of the little field, the doe and fawn came round to the spot where they had entered, and encountered the woman and her cow. The woman ran towards them, thinking to catch the fawn, which could not be more than a few weeks old; at all events, it was very small and young. The doe turned, and jumped at the fence, but whether her attention was distracted by her care for her young one, or whether she slipped on the turnips, could not be ascertained, of course; but certain it was that she pitched directly across the fence, her fore legs on one side, and her hind legs on the other, within ten yards of where the woman was standing. She at once dashed forward and seized hold of the doe's hind legs, and held *manfully* on to them. The doe kicked furiously, and the woman finally had to let go one leg, and put out her whole strength to retain possession of the other. This she succeeded in doing, and at the moment of my arrival her daughter, a girl of about twenty years old, muscular and tall, had just succeeded in finishing this most unequal contest by a vigorous stroke with the axe, which ended at once the struggles of the doe and her maternal anxiety for her fawn. The little creature came up quite close to its dead mother, and was easily captured. In fact it would not go away, but bleated and smelt about its dam most pitifully. We took the doe to the house and skinned her, and I had some of her meat for dinner. Her fawn became quite tame, and I offered the woman $4 for it for a pet for my sister's children. I had none of my own at that time. She declined selling it, and kept it as a pet about the house for years. It always wore a bell and red flannel collar to distinguish it from its wild playmates, who sometimes came to see it, being a female, and many a fine buck has paid the penalty of his life for the pleasure of a visit, the red collar always causing sufficient distinguishing mark to ensure its not being shot. At these seasons the bell was dispensed with. The collar, however, came off one day, and the owner shot her for a wild deer.

About that time, and for several years afterwards, deer were so plentiful that they could be shot at any time—almost, in fact, any week you could get a shot at one. I recollect, afterwards, seeing from a high elevation, in our own field, a herd of fourteen feeding on our young wheat, and a most beautiful sight it was, when my brother, creeping round in a ravine, came face to face with them all. It was evening, and the moment he appeared a splendid buck raised his head and looked at him for a second, then threw up the fan-like tail, and away the whole herd went over the fence, each taking a leap in its turn in the most beautiful manner imaginable.

To draw an old nail, first hit a blow with the hammer sufficiently hard to start it in; this breaks the connection with the wood which rust has made, and it is easily removed.

Plank walks about the house will save wet feet, colds, coughs and very likely heavy doctor's bills. Old boards, slabs, etc., with blocks nailed upon the under side, will answer very well.

One of the largest wheat growers of Alameda county, Cal., having had some experience in dealing with commission merchants, chartered a vessel this year himself, and has sent 1,200 tons of wheat direct to the Liverpool market.

A correspondent of the *Rural New Yorker* thinks that the safe, successful plan is to continue to cultivate hops, where the crop is established on good ground and in a good locality, notwithstanding the discouragements of the present and two preceding seasons.

At a late meeting of the New York Farmers' Institute, cranberry growing in New Jersey had a hearing, disclosing the fact that good judges estimated the crop in Ocean county at 25,000 bushels. The ruling price at present is $3 25 per bushel, but an advance on these figures is expected by the holders. There are two practical enemies of the cranberry; two classes of worms and grasshoppers. A flock of turkeys will do for the latter, and timely flooding for the former.

Steel Tooth Sulky Horse Rake

1st Prize, Provincial Fair, London, 1869!
1st Prize, Provincial Fair, Toronto, 1870!!

Will do more work, easier, cleaner, and better than the common rakes. It does not gather dead in the hay. Will rake over rougher ground. Is light and strong, well-made and nicely finished. The teeth are fine spring steel, independent of each other, and will yield to pass obstructions without bending or breaking. The best in use. Furnished *with* or *without* Plaster Sower attachment or Hay Tedder. For references, &c., send for circulars.

☞ Active Local Agents Wanted in every County.

TO BEE-KEEPERS.

HAVING taken the First Prize on my Bee Hives at every Provincial Fair, for the last seven years, they have gained a reputation unsurpassed by any hive in America. Such being the case, I now give notice that I shall not enter my hives for a prize at any coming Provincial Fair, believing their reputation as the best hive in the market is sufficiently established.

I am sending hives to England, the United States, and every part of the Dominion, and shall be pleased to fill any orders accompanied with the cash for Hives, Honey Extractors, Italian Bees and Queens and everything belonging to the Apiary. CANADIAN BEE-KEEPERS' GUIDE, post-paid, 25 cents.

☞ Bee-keepers residing in the Townships of Thorold and Sydney will hereafter send their orders to C. C. Chapin, Belleville, Ont., as he is now the owner of that territory. Those residing in the Counties of Lennox and Addington, to Allan Pringle, Selby, Ont., as he has purchased those counties.

Territory still for sale cheap.

THE AMERICAN BEE JOURNAL, Prince of *Bee Journals*, furnished to subscribers at $1.75, Dominion currency. No Bee-keeper should be without it.

THE JOSEPH HALL MACHINE WORKS,

(ESTABLISHED 1851,)

OSHAWA, ONTARIO.

THE JOSEPH HALL MANUFACTURING COMPANY

PROPRIETORS,

MANUFACTURE THE CELEBRATED

LEFFEL PATENT

DOUBLE TURBINE WATER WHEEL.

Our New Patent Iron Case or Flume.

We are the only manufactorers who can furnish the genuine LEFFEL WHEEL in Canada, as will be seen by the following certificate:—

SPRINGFIELD, Ohio, Dec. 25, 1868.

We take pleasure in informing the public of Canada, that we have sold and furnished Mr. F. W. Glen, of Oshawa, Ontario, Patterns, Forms, Drawings, Gangee, and all other necessary information to build our celebrated Double Turbine Water Wheel, invented by James Leffel, and known as the "Leffel Wheel." We have also obligated ourselves to furnish the same facilities for manufacturing to no other parties in Canada. Without the information we have given to Mr. GLEN, no one can successfully build our Wheels, and we advise parties in Canada to purchase our Wheels of no other manufacturer. Mr. GLEN's facilities are unsurpassed, and we feel sure that he will build a Wheel that will give perfect satisfaction. We therefore commend him to the public of Canada with entire confidence, feeling sure he will manufacture a Wheel in all respects equal to our own.

(Signed,) JAMES LEFFEL & CO.

WARRANTY.

We are prepared to furnish Water Wheels, Gears, Shafts, Pulleys, and all Machinery necessary to attach the Wheels to the Machinery they are intended to drive; and if, after two months' trial, they are not satisfactory, we will take all back, pay freight both ways, and refund any paymeats made to us thereon. Where parties are not satisfied with the Wheel, and cannot make a change at the time without loss to business, they may run the Wheel and Machinery a reasonable time without charge, not exceeding one year, in order that they may make a change without injury to their business.

Below are given the names of parties who are now using from ONE TO TEN each of our wheels; and we invite parties who wish to purchase to correspond with them.

Paper Cutters, Engine Governors, Shafting, Pulleys. Self-adjusting Hangers with Self-oiling Boxes. Castings of all kinds made in brass or iron. New Machinery of any kind made to order. Patterns of every description made when desired.

☞ All Machinery warranted to be made of first-class material in a thoroughly workmanlike manner.

Parties desiring further information, address F. W. GLEN, President, Oshawa, Ont.

v3-1-12t

New-York Tribune.

1871. Daily, Semi-Weekly and Weekly. 1871.

THE WEEKLY TRIBUNE,

The Paper of the People.

THE TRIBUNE aims to be pre-eminently a *Newspaper*. Its correspondents traverse every State, are present on every important battle-field, are early advised of every notable Cabinet decision, observe the proceedings of Congress, of Legislatures, and of Conventions, and report to us by telegraph all that seems of general interest. We have paid for one day's momentous advices from Europe by Cable far more than our entire receipts for the issue in which those advices reached our readers. If lavish outlay, unsleeping vigilance, and unbounded faith in the liberality and discernment of the reading public, will enable us to make a journal which has no superior in the accuracy, variety, and freshness of its contents, THE TRIBUNE shall be such a journal.

To Agriculture and the subservient arts, we have devoted, and shall persistently devote, more means and space than any of our rivals. We aim to make THE WEEKLY TRIBUNE such a paper as no farmer can afford to do without, however widely his politics may differ from ours. Our reports of the Cattle, Horse, Produce and General Markets are so full and accurate, our essays in elucidation of the farmer's calling and our regular reports of the Farmers' Club and kindred gatherings, are so interesting, that the poorest farmer will find therein a mine of suggestion and counsel, of which he cannot remain ignorant without positive and serious loss.

THE TRIBUNE has been, is, and must be a zealous advocate of Protection to Home Industry. Regarding habitual idleness as the greatest foe to human progress, the bane of human happiness, we seek to win our countrymen in masses from the ensnaring lures of Speculation, of Traffic and of always over-crowded Professions, to the tranquil paths of Productive Industry. We would gladly deplete our over-crowded cities, where thousands vainly jostle and crowd in misguided quest of "Something to Do," to cover prairies and plains with colonies absorbed in Agriculture, Mechanics and Manufactures, and constantly projecting into the blank, void wilderness the homes and the works of civilized Man. Holding the Protection of Home Industry by discriminating duties on imported Wares and Fabrics essential to the rapid, beneficent diffusion of Production in all its phases and departments, and so to the instruction of our people in all the gainful arts of Peace, we urge our countrymen to adhere to and uphold that policy in undoubting faith that the true interest, not of a class or a section, but of each section and every useful class, is thereby subserved and promoted.

We sell THE WEEKLY to Clubs for less than its value in dwellings for waste-paper; and, though its subscription is already very large, we believe that a Half Million more farmers will take it whenever it shall be commended to their attention. We ask our friends every where to aid us in so commending it.

AS A FAMILY NEWSPAPER,

THE WEEKLY TRIBUNE is pre-eminent. In addition to Reviews, Notices of New Books, Poetry, &c., we publish Short Stories, original or selected, which will generally be concluded in a single issue, or at most in two or three. We intend that THE TRIBUNE shall keep in the advance in all that concerns the Agricultural, Manufacturing, Minting, and other interests of the country; and that; for variety and completeness, it shall remain altogether the most valuable, interesting, and instructive NEWSPAPER published in the world.

No newspaper so large and complete as THE WEEKLY TRIBUNE was ever before offered at so low a price.

TERMS OF THE WEEKLY TRIBUNE.

To Mail Subscribers.

One copy, one year, 52 issues.....$2
Five copies.....9.

To ONE ADDRESS, all at one Post Office.

Ten Copies.....$1 50 each.

v3-1-1t

The Burlington and Mo. River R. R. Co.

Offer about 2,000,000 Acres

IOWA AND NEBRASKA LANDS

FOR SALE

On 10 Years' Credit, at 6 pr. ct. interest,

No part of Principal due for two years from purchase, and afterwards only one-ninth yearly.

Products will Pay for Land and Improvements.

The Liberal Credits given; Free Passes allowed; small annual payments required; the current market value of money, and profits on stock raising, prove these terms cheaper, easier and better than to buy U. S. land within railroad-land-limits at $2.50 per acre, while our prices range generally from 4 to 5, 6, 8 and 10 Dollars per acre. Quality and local advantages rule the price.

On these Generous Terms the industrious and competent can buy and pay for a good Farm and Home. In beginning, it is necessary to have money enough to pay six per cent. interest on the land, obtain provisions, build a cabin, buy a team and agricultural implements till crops are raised, which can be done the first season, by commencing in early Spring.

CIRCULARS giving full particulars are supplied gratis, and any wishing to induce others to emigrate with them, or to form a Colony, are invited to ask for all they want to distribute.

A SECTIONAL MAP, showing exact location of Lands for sale in Iowa, is sold for 30 cents, and a similar Map of Nebraska Lands is sold for 20 cents.

Apply to **GEO. S. HARRIS,**
Land Commissioner, Burlington & Mo. River R. R. Co.

For Iowa Lands, at BURLINGTON, IOWA.

For Nebraska Lands, at LINCOLN, NEBRASKA.

GREGORY'S

Illustrated Catalogue

OF

GARDEN AND FLOWER SEEDS.

Having in former years introduced to the public the Hubbard Squash, American Turban Squash, Marblehead Mammoth Cabbage, Mexican Sweet Corn, Phinney's Water-Melon, Brown's New Dwarf Marrowfat Pea, Boston Curled Lettuce, and other

NEW AND VALUABLE VEGETABLES,

with the return of another season I am again prepared to supply the public with Vegetable and Flower Seeds of the purest quality. My Annual Catalogue is now ready, and will be sent *free* to all. My customers of last year will receive it without writing for it. It abounds in fine engravings, many of which were taken from photographs of the vegetables themselves. It has not only all novelties, but all the standard vegetables of the farm and garden, (over one hundred of which are of my own growing,) and a carefully selected list of Flower Seeds.

All my seed is sold under three warrants,—1st: *That all money sent shall reach me.* 2d: *That all seed ordered shall reach the purchaser.* 3rd: *That my seeds shall be fresh, and true to name.* I invite all to send for catalogues, both for themselves and their friends.

JAMES J. H. GREGORY, MARBLEHEAD, MASS.

v3-1-3t

EPILEPSY OR FITS.

A SURE CURE for this distressing complaint is now made known in a Treatise (of 48 octavo pages) on Foreign and native Herbal Preparations, published by DR. O. PHELPS BROWN. The prescription was discovered by him in such a providential manner that he cannot conscientiously refuse to make it known, as it has cured everybody who has used it for Fits, never having failed in a single case. The ingredients may be obtained from any druggist. Persons desiring a copy may address DR. O. PHELPS BROWN, No. 21 Grand Street, Jersey City, N. J.

VINEGAR, HOW MADE FROM CIDER, Wine, Molasses or Sorghum, in 10 hours, without using drugs. For circular address F. I. SAGE, Vinegar Maker, Cromwell, Ct. v2-9-12t

DOMINION OF CANADA

V. R.

EMIGRATION

TO THE

PROVINCE OF ONTARIO.

To Capitalists,
Tenant Farmers,
Agricultural Labourers,
Mechanics,

DAY LABOURERS,

And all Parties desirous of Improving their Circumstances by Emigrating to a New Country.

THE attention of intending Emigrants is invited to the great advantages presented by the Province of Ontario. Persons living on the interest of their money can easily get eight per cent. on first-class security.

Tenant Farmers with Limited Capital

Can buy and stock a Freehold Estate with the money needed to carry on a small farm in Britain. Good cleared land, with a dwelling and good barn and outhouses upon it, can be purchased in desirable localities at from £4 to £10 Stg. per acre. Farm hands can readily obtain work at good wages. Among the inducements offered to intending Emigrants, by the Government, is

A FREE GRANT OF LAND

(WITHOUT ANY CHARGE WHATEVER.)

Every Head of a family can obtain; on condition of settlement, a FREE GRANT of two hundred acres of land for himself, and one hundred acres additional for each member of his family, male or female, over eighteen years of age.

All Persons over 18 years of age can obtain a FREE GRANT OF 100 ACRES.

The Free Grants are protected by a Homestead Exemption Act, and are not liable to seizure for any debt incurred before the issue of the patent, or for twenty years after its issue. They are within easy access of the front settlements, and are supplied with regular postal communication.

Registers of the Labour Market

And of Improved Farms for sale, are kept at the Immigration Agencies in the Province, and arrangements are made for directing emigrants to those points where employment can be most readily obtained. Several new lines of railway and other public works are in course of construction, or about being commenced, which will afford employment to an almost unlimited number of abourers.

Persons desiring fuller information concerning the Province of Ontario, are invited to apply personally, or by letter, to the Canadian Government Emigration Agents in Europe, viz.: Wm. Dixon, 11 Adam Street, Adelphi, London, W. C.; J. G. Moylan, Dublin; Charles Foy, Belfast; David Shaw, Glasgow; and E. Simays, Continental Agent at Antwerp.

Also to the Emigration Agents in Canada, viz:

John A. Donaldson, Toronto; R. H. Rae, Hamilton; Wm. J. Wills, Ottawa; Jas. Macpherson, Kingston; L. Stafford, Quebec; J. J. Daley, Montreal; E. Clay, Halifax, Nova Scotia; Robert Shives, St. John, and J. G. G. Layton, Miramichi, New Bronswick, from whom pamphlets issued under the authority of the Government of Ontario, containing full particulars in relation to the character and resources of, and the cost of living, wages, &c., in the Province, can be obtained.

JOHN CARLING,
Commissioner of Agriculture and Public Works for the Province of Ontario.

Department of Immigration,
Toronto, October, 1869. v2-2-12t.

Markets.

Toronto Markets.

"CANADA FARMER" Office, Jan. 12th, 1871.

FLOUR AND MEAL.

The market in produce has been quiet, with few transactions. The tendency of prices is upward, and holders, expecting a further rise, are unwilling to sell. The following are present quotations:—

Flour—Superfine, $5 25 to $5 30; Fancy, $5 40 to $5 50; Spring Wheat, extra, $5 30 to $5 40, Extra, $5 75 to $6; Superior Extra, $6.

Oatmeal—$6.20 to $5.25.

Cornmeal, in small lots—$3.75 to $4.25.

Bran, in ton lots—$15.

GRAIN.

The dulness provailing in Flour, and for similar reasons, characterises the grain market.

Wheat—Soules, $1 20 to $1 25; Spring, $1 15 to $1 16, Spring Midge Proof, $1 15 to $1 16; Treadwell, $1 16 to $1 18.

Barley—Inferior, 50c to 55c; Do., bright, 60c to 63c.

Oats—43c to 44c.

Peas—68c to 70c.

Rye—70c.

HAY AND STRAW.

The market has been pretty well supplied, and the prices range for *Hay* from $9 to $13.50; *Straw*, $7 to $8.

THE CATTLE MARKET.

Trade is recovering somewhat from the dulness which usually prevails at this season of the year.

Beeves from $3.25 to $5 per 100 lbs.

Sheep from $3 to $7.

Calves from $3.50 to $8.

Lambs from $2.75 to $5.

PROVISIONS.

Pork—Mess, $19 to $19 50.

Bacon—Cumberland cut, 6½c to 10c.

Hams—Salted, 10c to 11c.; Smoked, new; 11c to 12c.

Lard—In tinnets, 12c to 13c; In tierces, 11c to 12c.

Butter—Choice dairy, 17c to 19c.

Cheese—Recsor's Stilton, 18c; Royal Arms, 17c.

Eggs—Fresh, 22c to 25c per dozen.

Dried Apples—6c to 7c.

Hops—Superior, 15c to 16c; Ordinary, 8c to 12c.

Salt—Goderich, $1 55; American, $1 85; Liverpool, per bag, 75c to 80c.

PROVINCIAL MARKETS.

Montreal.—*Flour*—Extra, $6.30 to $6.35; Fancy, $5.90 to $6; Welland Canal Superfine, $5.75; Superfine No. 1 Canada Wheat, $5.70 to $5; No. 1 Western Wheat, $5.70 to $5.75; No. 2 Western Wheat, $5.30 to 6.40; Bag Flour $2.60 to $2.60. *Wheat*—Western, $1.19 to $1.23. *Oats*—Per 32 lbs., 43c to 45c. *Barley*—Per 48 packed, 14c. to 17c. *Ashes*—Pots, $6 to $6.05; Pearls, $5 to $6.05. *Pork*—Mess, $19.50 to $20; Prime Mess, $16; prime, $15. *Dressed Hogs*—$6.62 to $7.

London, Jan. 10.—*Spring Wheat*, $1.18 to $1.25. *Red Fall Do.*, $1 to $1.16; *White Do.*, $1.10 to $1.25. *Barley*, 45c to 60c. *Peas*, 62½c to 70c. *Oats*, 41c to 42c. *Corn*, 65c to 68c. *Rye*, 40c to 50c. *Clover Seed*, $4.50 to $5. *Dressed Hogs*, $6 to $6.70.

Hamilton, Jan. 10.—*Wheat*—Delhi, $1.28 to $1.30; Soules, $1.25 to $1.27; Treadwell, $1.22 to $1.25; Winter Red, $1.18 to $1.20; Amber, $1.18 to $1.20; Spring, $1.17 to $1.20. *Barley*, 50c to 52c. *Peas*, 70c to 72c. *Oats*, 45c to 47c. *Flour*, Superfine, $6 to $6.50; Extra, $6.50 to $6; Superfine No. 1, $5 to $5.50; do. No. 2, $4.50 to $5; fine, $4. *Oatmeal*, per 100 lbs., $1.75 to $2. *Butter*, in rolls, 20c to 25c; do., tub, 17c to 19c. *Cheese*, 12c to 13c. *Eggs*, 30c. *Honey*, 25c. *Apples*, 60c to 90c. *Potatoes*, 51c to 60c. *Green Hides*, No. 1, inspected, $6.50; do No 2, $7.50; Calfskins, green, 10c; do dry, 15c to 20c; lambskins, 50c to $1; pelts, 60c to $1.

Guelph, Jan. 10.—*Wheat*—Fall, per bush, $1.18 to $1.27; Spring do., $1.18 to $1.20; Treadwell do, $1.16 to $1.22. *Oats*, 35c to 41c. *Peas*, 64c. *Barley*, 45c. to 50c. *Hay*, per ton, $8 to $9.50. *Straw*, per ton, $3 to $4. *Wood*, per cord, $3.50 to $4. *Eggs*, per doz., 20c to 24c. *Butter*, storepacked, per lb., 12c to 18c; dairy-packed, per lb, 15c to 16c. *Potatoes*, per bag, 40c to 50c. *Apples*, per bag, 40c to 50c. *Pork*, per 100 lbs, $5.88 to $6.75.

[illegible]ONTRIBUTORS—PR[illegible]
DRAINAGE EDITO[illegible] M.
ARCHITECTURAL [illegible]
ENTOMOLOGICAL [illegible]
V[illegible]Y E[illegible] Edin.
[illegible]DITOR[illegible].

The Conductors of THE CANADA FARMER will continue to l[illegible]nestly f[illegible]r the [illegible]llo[illegible]nds—

To arouse attention, by frank and temperate discussio[illegible], to all questions, scientific, commercial, legislative or otherwi[illegible], specially affecting the farming interests.

To stimulate the agriculturists of o[illegible] country to ad[illegible] proved system of hu[illegible]ndry, by blending the [illegible]essons of modern science with the practical experience of the Canadian farmer.

To bring under the attention of our farmers all improvements a[illegible]nd abroad, worthy of adoption, affectin[illegible] the [illegible]ent of Field Crops—the Barn Yard—the [illegible]e Orchard—th[illegible] Poultry Yard—the Ap[illegible] Kit[illegible]n Gard[illegible]—and the Flower Garden; and to [illegible]it terest in the [illegible] of Rural Architecture [illegible] rden[illegible], and all that concerns the domesti[illegible]onomy [illegible] House.

To k[illegible]d port a[illegible] improvements in Agricultural Machinery, [illegible] inventions, and promot[illegible] the adoption of all [illegible]ving machines, in the [illegible]k of the farm and garden.

To keep prominently under attention all that specially concerns the Dairy Farmer and the Grazier—the best breeds of Cattle —the best systems of feeding—the most approved processes of cheese and butter making—the best mode of packing—and the best markets to sell in.

To keep prominently in vi[illegible] whatever is [illegible]ting to [illegible] heep-raiser and Wool-grower—t[illegible] b[illegible]t adapted [illegible] o[illegible] climate—the best system of winter and summer [illegible] ment—and the varying prospects of [illegible]e [illegible]l [illegible]

To [illegible]ord the Farmers of Canada an ever-open medium for addressing their brother Agriculturists throughout the Dominion, suggesting me[illegible] of common interest and advantage, and[illegible]li[illegible]iting [illegible]rmation or advice on practical questions of d[illegible]ulty [illegible] doubt.

To [illegible]eport co[illegible]ly the proceedings at Agricul[illegible] [illegible]l and [illegible]l throughout the Provinces—[illegible] progr[illegible] of the Herds and Flocks of pro[illegible]; and record the importation of Th[illegible]red [illegible]m abroad.

To watch and report carefully and [illegible]tly t[illegible]ual state and probable [illegible]pects of the P[illegible] [illegible]at home and abroad; a[illegible] speci[illegible]lly prom[illegible]a[illegible] m[illegible]nts designed to secure the [illegible] pric[illegible] h[illegible]rkets for Canadian Farm P[illegible]nce.

To afford the Farmers of the Dominion a common medium, where [illegible] who have for sale Live Stock, or Seed, Grain or L[illegible] [illegible] may wish to buy such, can make their d[illegible] directly to the whole farming population of Ca[illegible]

THE CANADA FARMER will continue to be issued on the fifteenth day of each month,—the form will be the same as now—and each number will contain
